PROCEEDINGS

of the 78th American Academy of Forensic Sciences Annual Scientific Conference

The *Proceedings* of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS). It is devoted to the publication of the abstracts of technical oral papers and posters presented at the AAFS Annual Scientific Conference. These include various branches of the forensic sciences such as anthropology, criminalistics, digital evidence, forensic nursing, engineering, jurisprudence, odontology, pathology, psychiatry, questioned documents, and toxicology. Similar submissions dealing with forensic-oriented aspects of the social sciences are also included.

Please note that some of the abstracts included in the *Proceedings* deal with topics, results, and/or conclusions that are controversial. The publication of abstracts does not imply that the AAFS, its sections, or the individual section program chairs/committee members have verified or agree with the studies, results, and/or conclusions of each abstract. During the process of planning a scientific program, it is impossible to "peer-review" each abstract and presentation to the degree that is accomplished during manuscript review. Abstracts and presentations are accepted, in part, so they can be critiqued and reviewed by other scientists. Thus, a forum is created to discuss controversial issues. The views expressed in this publication are not those of the AAFS. The data and opinions appearing in the published material were prepared by and are the responsibility of the contributor(s), not of the AAFS nor its respective employees, employers, officers, and agents. The AAFS does not supply copies of meeting papers. Please write directly to individual authors to obtain copies of specific papers. Presentation of some abstracts may have been scheduled or canceled after the publication of this document.

English is the official language of the AAFS and its meetings; neither oral nor written translations will be provided. Copyright 2026 by the AAFS. Unless stated otherwise, non-commercial photocopying of editorial material published in this periodical is permitted by the AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained from the AAFS.

S1 Young Forensic Scientists Forum: Unmasking the Voodoo—Empowering the Next Generation of Truth-Seekers

Emily Rue, PhD, Department of Army Criminal Investigation, Forensic Exploitation Division, Atlanta, GA; Amy Carney, PhD*, California State University San Marcos, San Marcos, CA; Marla Carroll, BS*, Forensic Video & Audio Associates, Inc., Atlanta, GA; Claire Cartozzo, PhD*, MRI Global, Louisa, VA; James Caruso, MD*, DPHE Office of the Medical Examiner, Denver, CO; Isabelle Cohn, BASc*, Innocence Project, New York, NY; Joanna Collins, MFS*, LINUS Investigations and Consulting, San Antonio, TX; Christopher Ehrhardt, PhD*, Virginia Commonwealth University, Richmond, VA; Beth Saucier Goodspeed, MS*, Lasell University, Auburndale, MA; Cheryl Hunter*, American Academy of Forensic Sciences, Colorado Springs, CO; John Paul Jones II, MBA*, National Institute of Standards and Technology, Gaithersburg, VA; Brooke Kammrath, PhD*, University of New Haven, West Haven, CT; Laura La Cagnina, DNP, MSN, RN*, Forensic Nurse/Educator, Marietta, GA; Tiffany Roy, JD, MSFS*, ForensicAid, LLC, West Palm Beach, FL; Shivani Sanger, MSc*, Liverpool John Moores University, Liverpool, England; Kathryn Seigfried-Spellar, PhD*, Michigan State University, East Lansing, MI; April Solomon, MFSF*, Jefferson Parish Sheriff's Office, Regional DNA Laboratory, Metairie, LA; Jeffery Tomberlin, PhD*, Texas A&M University, College Station, TX; Elora Wall, MS*, Jefferson Parish Sheriff's Office, Crime Laboratory, Metairie, LA; Sara Zapico, PhD*, New Jersey Institute of Technology, Newark, NJ*

Learning Objective: The YFSF offers students and young professionals the opportunity to interact with professionals in the forensic science community as they begin their careers. This session presents attendees with the chance to learn about the multitude of careers available in forensic science as well as develop professional skills that are essential for the job-hunting process. Our mission is to provide the education, mentorship, and resources necessary to champion students and young forensic scientists to promote interest, membership, and participation with AAFS and the forensic science community for years to come.

Impact Statement: The YFSF provides students and young professionals with less than five years of experience an opportunity to network, collaborate, and learn from fellow peers and experts in the field. This session will prepare attendees for a successful career in their discipline of choice and allow them to look from the outside-in as they evaluate themselves and their future impact on forensic science. Our mission is to provide education, mentorship, and resources to students and burgeoning forensic scientists in order to promote interest and longevity in the field and to encourage participation and advancement in the AAFS.

Abstract Text: This year, the American Academy of Forensic Sciences (AAFS) is celebrating 78 years of global engagement. The overall theme of the conference is *Back to the Basics: The Fundamentals of Forensic Science*. In the past few years, we have seen more people exonerated for a multitude of reasons, including fallacious science, improper investigation and analysis, and misrepresentation of results. AAFS President Joanna Collins' plan is to focus on the ethical application of science, standards development and implementation, implementation of the scientific method, and a duty to remain unbiased. Our Special Session theme, Unmasking the Voodoo: Empowering the Next Generation of Truth-Seekers, was chosen to invigorate young forensic scientists and demonstrate how education and training play a vital role in the success of forensic science. This full-day session will show young forensic scientists that their contribution matters and that the decisions they make today can have a positive impact on the scientific community at large.

This year, the YFSF is excited to present an outstanding group of speakers. These distinguished presenters have been carefully selected to provide exceptional mentorship to attendees through topics such as how to use standards to increase your confidence, pathways for forensic nurses, a path to leadership, and how research plays an integral role in forensic science. The session will also include thoughtful demonstrations on assessing one's professional goals, establishing what success looks like for a young forensic scientist, and thinking about one's responsibilities as a mentor and leader as one advances into a career. The YFSF Special Session provides an inclusive atmosphere for young forensic scientists to have the opportunity for professional growth/development and scientific engagement with esteemed colleagues.

Through these presentations, attendees will hear from experienced practitioners as they discuss their extensive education, training, and experiences that have led to success in their field of study. These presentations include case-driven research, innovative methodology, scientific studies, and personal stories. Through this session, the YFSF aims to integrate young professionals into the field as they begin their journey into forensic science. The YFSF offers two additional opportunities for young professionals and students: the Bring Your Own Posters (BYOP) Session and the Bring Your Own Slides (BYOS) Session.

We are excited to announce that for the fourth year, we have collaborated with The Center for Forensic Science Research and Education (CFSRE) to honor and award two outstanding scientists for their contribution to forensic science. Finally, the session will host a resume review workshop, so do not forget to update your resume and bring printed copies with you to the session!

S2 Interdisciplinary Symposium: Sustaining the Science and the Scientist: Foundations for the Future

Katharine Pope, MA, SNA International, (supporting the DPAA mission), Fruitland, MD; Laura Labay, PhD*, NMS Labs, Horsham, PA; Nathaniel Adams, BS*, Forensic Bioinformatic Services, Dayton, OH; David Annas, MD*, Forensic Psychiatry Consulting, LLC, Alexandria, VA; Ryan Backmann*, Project: Cold Case, Jacksonville, FL; Garry J. Bombard, PhD*, Garry Bombard Forensic Consulting, Chicago, IL; Stacey Chepren, MSc*, United States Air Force, International Association of Coroners & Medical Examiners, Tucson, AZ; Laura Gaydosh Combs, PhD*, University of New Haven, West Haven, CT; Jan M. Gorniak, DO*, World Peace Forensic Consulting, LLC , Tallahassee, FL; Krystal R. Hans, PhD*, Department of Entomology, Purdue University, West Lafayette, IN; Sherri Kacinko, PhD*, NMS Labs, Horsham PA; Dustin Nolen, PE*, Vista Engineering & Consulting, LLC, Birmingham, AL; Raymond Thompson, PhD, PE*, Vista Engineering & Consulting, LLC, Birmingham, AL; Joe Treviño*, New York Police Department, New York, NY; Jalika Waugh, PhD*, Emergency Management/Public Safety, Pinellas County Schools, Largo, FL; Teresa 'Lilly' White, PhD*, Bone & Stone Anthrosciences, LLC, Bigfork, MT*

Learning Objectives: This session features presentations and professional discussions across AAFS sections that address the multifaceted challenges forensic scientists encounter throughout their careers. Beyond technical expertise, sustaining excellence in forensic science requires deliberate attention to ethics, education, communication, and well-being. Speakers will examine strategies to uphold professional standards, protect personal well-being, and maintain public confidence in forensic science. Psychological factors, including the infallibility complex and imposter syndrome, will be explored alongside approaches for strengthening community support and fostering workplace well-being. The session will also address long-term career sustainability through mentorship and continuous quality improvement. By integrating multiple perspectives, the program seeks to cultivate a more resilient, ethically grounded, and sustainable forensic science workforce.

Impact Statement: Attendees will acquire critical perspectives on the professional and personal challenges that influence the trajectory and longevity of careers in forensic science as well as strategies for sustaining both. The session is structured around two interrelated themes: the development of the practitioner and the advancement of the practice, with particular attention to long-term sustainability. Presenters will underscore the importance of well-being in both occupational and personal domains, emphasizing its direct impact on the integrity and effectiveness of forensic science from analytical testing and data interpretation to the delivery of expert testimony in judicial settings. Topics will also include learning from system failures, fostering STEM education, and strategies for maintaining competency throughout a career. Finally, the session aims to promote interdisciplinary dialog on how practitioners can support one another, ensuring the continued evolution of forensic science while enabling AAFS members to thrive and contribute meaningfully to the field.

Abstract Text: The 2026 AAFS Annual Scientific Conference's Interdisciplinary Symposium (IDS) highlights the theme *Back to Basics* through a dynamic program including a keynote address, five presentations focused on "Building the Practice," and five presentations focused on "Building the Practitioner," with dedicated time for discussion. IDS keynote speakers are Krystal Hans from Purdue University and Ryan Backman from Project Cold Case. Their presentations will address the importance and benefits of an interdisciplinary approach to the investigation of cold cases. The first IDS panel, moderated by Katharine Pope, delves into "Building the Practice" and features insights from Jalika Waugh, Garry Bombard, Raymond Thompson, Dustin Nolen, David Annas, and Laura Gaydosh Combs. This session explores strategies to strengthen forensic science as a discipline. Topics include promoting STEM education, understanding *Daubert* standards, maintaining competency for testimony, and learning from failures in casework. The second IDS panel, moderated by Laura Labay, focuses on "Building the Practitioner" and features insights from Sherri Kacinko, Joe Trevino, Jan Gorniak, Stacy Chepren, and Theresa White. This session addresses personal and professional challenges faced by forensic practitioners. Topics include creating welcoming workplaces and preventing burnout, managing stress, promoting inclusion among practitioners, understanding and mitigating imposter syndrome in courtroom settings, and delivering difficult communications such as death notifications. Together, these sessions will explore the interplay between advancing rigorous practices and cultivating resilient practitioners, reinforcing the collective responsibility to ensure that all AAFS sections of forensic sciences remain credible, sustainable, and responsive to the needs of justice.

CB1 Fiction vs. Science: The Yara Gambirasio Case on *Netflix*

Michele Vaira, JD, Vaira Law Office, Foggia, Puglia, Italy; Luciano Garofano, PhD*, Italian Academy of Forensic Science, Parma, Emilia-Romagna, Italy*

Learning Objectives: After attending this presentation, participants will understand how journalistic investigations and TV dramas can mislead the perception of the facts established in criminal trials, even when the judgments are final.

Impact Statement: This presentation will highlight the danger that biased information may influence public opinion on the fairness of judicial decisions and, in jury-based legal systems, sway the jury's perspective.

Abstract Text: The case concerns the murder of Yara Gambirasio, a 13-year-old girl, which took place on 26th February 2010 in a small town called Brembate di Sopra (Bergamo-Italia). Three months after her disappearance, on February 25, 2011, her dead body was found in a field, frozen and partially decomposed. Yara had several stab wounds, including to her throat, but she died by starvation and cold. Biological material from a third person was found on her underwear, from which the DNA profile was extracted.

To identify the unsuspected culprit, the investigators conducted an extensive population screening program. They began with DNA databases and collected over 20,000 swabs from men and women living in that specific geographical area. Using a multidisciplinary approach based on the full integration of traditional and scientific investigations, it was possible to identify a subject whose DNA matched perfectly with the one identified on Yara's clothes. On July1, 2016, after a long trial, the Court of Assizes of Brescia sentenced Massimo Bossetti to life imprisonment. The sentence was confirmed both at appeal and by the Supreme Court.

In the *Netflix* docuseries, filmed after the sentence became final, the authors attempted to cast doubt on the decision of the Italian judiciary, carefully selecting and editing various contributions from the protagonists of the story, including the condemned man. In the series, the figure of the Public Prosecutor is particularly criticized, especially through the contribution from journalists who openly claim innocence. Through these contributions, the fundamental importance of the DNA traces belonging to Massimo Bossetti found on the victim's clothes is minimized. Paradoxically, the need to pursue other investigative leads is emphasized, even though these leads were clearly unfounded in the investigative and procedural reality.

This presentation will briefly summarize the facts, discuss the critical issues of the investigation, and highlight the inconsistency of the doubts raised in the series. It will also underscore the danger that non-impartial information, which arbitrarily suggests a sensational miscarriage of justice, can influence public opinion on the correctness of judicial decisions. In judicial systems where there is a jury, this can sway its orientation and foster distrust in the justice system.

CB3 Reducing Communication Barriers in the Use of the NIST-OSAC Verbal Scale: Focus on Reporting Glass Associations

Lauryn C. Alexander, PhD, West Virginia University, Morgantown, WV; Sarah E. Wagner, JD*, West Virginia University College of Law, Morgantown, WV; Melissa Giggenbach, JD*, West Virginia Innocence Project Clinic, Morgantown, WV*

Learning Objectives: By attending this session, attendees will: (1) discuss current issues between criminal lawyers and forensic scientists on how to properly convey the weight of the evidence using the verbal scale of the National Institute of Technologies-Organization of Scientific Area Committees (NIST-OSAC) trace subcommittee; (2) discuss the importance of pre-trial preparation and communication and propose ways forensic scientists can articulate the verbal scale; (3) know what questions to ask (and provide an explanation of why they should be asked) during direct examination of a trace evidence expert (these will be based on the simulation from the overview); (4) know what questions to ask (and provide an explanation of why they should be asked) during cross-examination of a trace evidence expert (these will be based on the simulation from the overview); and (5) create a mock transcript of a direct-exam and cross-exam of a trace evidence expert using a simulated case study.

Impact Statement: Currently, there is no manual, set of guidelines, or a standard operating procedure to reduce the communication barrier between trace evidence analysts and criminal lawyers. However, the issues with forensic science and its integration into the legal system must be addressed, specifically with the use of the verbal scale to report on the weight of the evidence. Many have published on the misinterpretation of likelihood ratios reported for DNA evidence, but it has not been reported for trace evidence, particularly glass and paint. Furthermore, the NIST-OSAC's verbal scale has been developed and proven useful but has not been integrated into reporting guidelines or taught to attorneys. This manual could be useful for lawyers planning to direct or cross-examine trace evidence analysts who use this verbal scale. Reporting with associations helps the scientist properly convey their results, while also reducing the risk of confusing attorneys, jurors, and judges alike.

Abstract Text: Forensic science and criminal law work hand-in-hand for our justice system. Unfortunately, there is a common issue with the misunderstanding and misinterpretation of forensic evidence due to the communication barriers present between the two fields. Simply put, lawyers have a difficult time understanding the weight of forensic evidence, and forensic scientists struggle to reduce their technical terms into layman's terms. Although this applies to most forms of forensic science, this manual aims to reduce the communication barriers between lawyers and scientists concerning the way glass and paint associations are reported.

This manual builds upon the case studies from the dissertation by Dr. Lauryn C. Alexander, entitled *Strengthening the Interpretation of Glass and Paint Evidence Through the Study of the Random Frequency of Occurrence and Analytical Information*, in order to reduce duplicative results.[1] In this manual, the intersection of forensic science and criminal law will be discussed broadly, including a background on trace evidence and the analysis of glass.[1] The mock crime scenes from Alexander's dissertation will be referenced and explained, followed by the current issues causing communication barriers. Discussion of the importance of pre-trial preparation and proposals for articulating the verbal scale will be highlighted. The NIST-OSAC verbal scale will be shared for both glass and paint associations before diving into the ways to conduct a direct examination and cross-examination of the forensic scientist.[2] Finally, a mock transcript using the simulated case study will be provided and analyzed. The goal of this manual is not only to solve the communication issues between forensic scientists and criminal lawyers, but also to merge the two fields in order to better serve justice and create a foundation of understanding for all.

CB4 From Investigation to Conviction: Combined Forensic and Investigative Efforts in an Infant Death Due to Diphenhydramine Toxicity

Nathan Shaller, MD, Clark County Office of the Coroner/Medical Examiner, Las Vegas, NV*

Learning Objectives: By attending this session, attendees will be able to: (1) describe key autopsy findings in fatal toxicity cases, including in cases due to diphenhydramine; (2) explain the role and importance of interdisciplinary collaboration, including forensic pathologists, toxicologists, death investigators, and law enforcement; and (3) extrapolate on collaboration and discuss the medicolegal significance of comprehensive death investigation in pediatric homicide cases and how coordinated efforts impact legal outcomes.

Impact Statement: This case highlights the interdisciplinary efforts on behalf of the forensic pathologist, toxicologist, coroner investigator, and law enforcement required to determine a rare homicidal manner of death for a pediatric toxicological death that ultimately resulted in conviction.

Abstract Text: Pediatric toxicological deaths present significant diagnostic and investigative challenges. In particular, homicides related to diphenhydramine toxicity in infants are rare.[1] This presentation describes the case of a 5-month-old male whose death was initially reported as a probable co-sleeping incident. Early scene investigation by the Coroner's Office and local law enforcement's Department of Abuse and Neglect included a doll reenactment and raised initial concerns. Autopsy findings revealed minor frontal subscalpular hemorrhages and abrasions on the neck and forehead. Neuropathological examination identified subdural membranes, basilar subarachnoid hemorrhage, cervical spinal cord epidural, and intradural hemorrhages. Toxicological analysis revealed lethal concentrations of diphenhydramine in multiple postmortem specimens.

Coordinated efforts by all parties involved testing of additional specimens for toxicologic analysis and escalation by Abuse and Neglect to a homicide investigation by law enforcement. Together, corroborative evidence indicated that the infant was deliberately administered diphenhydramine. The autopsy findings, toxicological data, and scene investigation led to the classification of the manner of death as homicide. After a preliminary trial, the defendant subsequently accepted a plea agreement and is currently serving a term of incarceration.

This case underscores the critical importance of interdisciplinary collaboration among forensic pathologists, toxicologists, coroner investigators, and law enforcement in resolving complex pediatric deaths. This presentation will also address additional educational points as needed to advance the discussion, which includes co-sleeping and the doll reenactment, pediatric intracranial hemorrhage, the recent National Association of Medical Examiners (NAME) recommendations on undetermined pediatric deaths, and court testimony in toxicological homicides. The successful legal outcome in this case highlights how thorough forensic investigation and interagency cooperation can bring clarity to ambiguous death scenes and ensure justice for vulnerable victims.

CB5 Air Crash Management and Victim Identification Prior to DMORT

John P. Kenney, DDS, MS, Davidson County Medical Examiner's Office, Nashville, TN*

Learning Objectives: This session will: (1) review management and identification procedures in late 20th-century accidents, (2) present the origins of the Disaster Mortuary Operational Response Team (DMORT), and (3) give recognition to the forensic scientist who participated and directed identifications prior to personal or desktop computers and associated identification software.

Impact Statement: In keeping with the theme of the meeting, this presentation will review, particularly for younger members of the Academy, the effort needed prior to the inception of DMORT to respond to a mass fatality incident and pay tribute to the senior and deceased members of the academy that paved the way for modern and rapid identification of victims, particularly in air crash incidents.

Abstract Text: Commercial air carrier accidents, with their immediate tragic newsworthiness and effect not only on a local community but the nation as a whole or even worldwide, occur with little or no warning. Fire, police, and then local coroners or medical examiners were forced to respond and literally create from scratch a morgue and identification center in the days before DMORT and its three portable morgues. Through the efforts of Tom Shepardson and others and starting with the National Foundation for Mortuary Care, the herculean effort calling on all manner of resources to assemble the space, equipment, and personnel needed was simplified into a unified effort now known as the Disaster Mortuary Operations Response Team. This paper will examine a number of these earlier incidents and pay tribute to the pioneers within the forensic science community, particularly Anthropology, Odontology, and Pathology, who were responsible to respond, recover, process, identify, and release the properly named victims back to their next of kin in a timely manner. Incidents reviewed will include the Tenerife, Chicago, Milwaukee, Washington, DC, and Roselawn, IN events. AAFS Members played a key role in all these events, some members at multiple events. Many participating AAFS members have gone before us and left this world a better place, and a number that are still active or retired members of the Academy also served as operational leaders and were our mentors and teachers. This presentation is a tribute to all of those who responded in the past and those who respond today.

CB7 Challenging Probabilistic Genotyping and DNA-TPPR Assumptions: A Case Study From *Minnesota vs. Porter*

Cynthia Cale, MSc, DNA Mavens LLC, Cleveland, TX*

Learning Objectives: Attendees will learn how limitations in probabilistic genotyping software validation, specifically contributor number assumptions, can affect the reliability of DNA evidence interpretation. This presentation will also explore the potential for sub-source likelihood ratios to be misinterpreted at the activity level. It will emphasize the importance of clearly communicating such limitations in forensic reports and testimony.

Impact Statement: This presentation will help forensic practitioners, attorneys, and stakeholders recognize the importance of adhering to software validation boundaries and properly contextualizing probabilistic results. It will promote more transparent and scientifically responsible communication of forensic DNA findings to prevent misinterpretation by courts and juries.

Abstract Text: In the case of *State of Minnesota v. Porter*, DNA evidence recovered from a firearm and its magazine played a pivotal role in the prosecution's case. The swabbing from the firearm was interpreted as a five-person mixture. While the true number of contributors cannot be known, the DNA profile likely exceeded five contributors, thereby falling outside the validated parameters for STRmix™ interpretation.[1,2] Despite this, the laboratory proceeded with probabilistic genotyping using STRmix™ and reported a likelihood ratio supporting the hypothesis that the defendant was a contributor rather than not a contributor.

The absence of diagnostic flags or software errors does not confirm the appropriateness of the analyst's assumptions regarding the number of contributors or the hypotheses tested. STRmix™ will generate likelihood ratios based on the input parameters provided. In this case, the laboratory treated the lack of diagnostic warnings as confirmation that its five-person assumption was valid, without clearly addressing the possibility that the mixture exceeded the validated limits of the software. This raises concerns about the reliability of the statistical output and the risk of overstating the strength of the DNA evidence if presented during trial.[3]

The swabbing from the firearm magazine yielded approximately 180 pg of DNA, an amount within the range reported in the literature for both direct and indirect transfer events. Because it is not possible to distinguish between direct and indirect transfer based on DNA quantity alone, the strength of the sub-source likelihood ratio must be interpreted with caution. The concern in this case is that, if the sub-source likelihood ratio were presented at trial without appropriate context, it could be misinterpreted by the jury as evidence of direct handling, thereby elevating a sub-source inference to the activity level.[4]

This case illustrates the importance of adhering to validated parameters and providing transparent, scientifically grounded interpretations. When probabilistic genotyping software is used at the edge or outside of its validated limits, it is essential that limitations be clearly disclosed and alternative explanations considered. Returning to the foundational principles of forensic DNA interpretation is critical to ensuring that the resulting conclusions are reliable, scientifically defensible, and ethically communicated.[1,2,4]

DD1 Vicarious Trauma and Cognitive Restructuring in Forensic Professionals: A Comparative Psychometric Study of Risk and Protective Factors

Maria Ludovica Lo Bianco, BASc, Mercatorum University, Palermo, Sicilia, Italy; Antonina Argo, PhD*, University of Palermo, Palermo, Sicilia, Italy; Stefania Zerbo, PhD, University of Palermo, Palermo, Sicilia, Italy; Ginevra Malta, PhD*, University of Palermo, Palermo, Sicilia, Italy*

Learning Objectives: By attending this presentation, participants will be able to: (1) define Vicarious Trauma (VT) and distinguish it from related constructs such as burnout and compassion fatigue, based on established theoretical models; (2) describe the cognitive impacts of VT in forensic professionals, with specific reference to changes in belief systems and emotional regulation mechanisms; (3) interpret comparative psychometric data regarding emotional symptoms, cognitive restructuring, coping strategies, and resilience between exposed and non-exposed groups; (4) evaluate the role of individual and organizational protective factors in mitigating the effects of VT and promoting professional well-being; and (5) identify implications for clinical practice and organizational policy, including the importance of supervision, targeted training, and preventive strategies in forensic settings.[1-3]

Impact Statement: This presentation will provide the forensic science community with novel insights into the cognitive and emotional consequences of VT in professionals regularly exposed to traumatic material. By offering comparative psychometric data and highlighting patterns of cognitive restructuring rather than overt psychopathology, the study challenges traditional views of trauma impact and emphasizes the subtle yet pervasive effects on professional functioning. The findings underscore the critical need for structured organizational support, supervision, and resilience-building strategies within forensic institutions. This research contributes to shaping evidence-based policies and interventions aimed at safeguarding the mental health of forensic practitioners and ensuring long-term professional sustainability.

Introduction: VT is now recognized as a stress-inducing phenomenon among those in the helping professions, especially those who are regularly exposed to indirect traumatic content. The theoretical models proposed by Pearlman and Mac Ian, Figley, and Bride highlight its cognitive nature, differentiating it from burnout syndrome and compassion fatigue, emphasizing the contagious nature of the traumatic experience, which passes from the person being helped to the helper.[1-3] This study explores the impact of VT in forensic practitioners who are regularly exposed to traumatic content through post-mortem investigations and case reconstructions.

Methods: The design is a comparative cross-sectional study between two matched groups: a target group of forensic practitioners (N = 24) and a control group (N = 17) of individuals not professionally exposed to traumatic material. All participants completed four validated psychometric scales to assess: (1) depressive, anxious, and intrusive symptoms; (2) self-perceived changes in core cognitive beliefs since the onset of employment; (3) defensive and professional coping strategies; and (4) protective factors and resilience. Means, standard deviations, and percentile distributions were calculated and compared between groups.

Results: Scale 1 (emotional symptoms) showed moderate levels in the target group (M = 2.23; SD = 0.54), with low variability. Scale 2 (changes in cognitive beliefs) had a value of 2.90 (SD = 0.85) in the target group and 2.98 (SD = 1.08) in the control group, with greater variability in the latter. Scale 3 (defensive/professional strategies) indicated greater use in the target group (M = 2.46) than in the controls (M = 1.88). Scale 4 (resilience and protective factors) showed a higher score in the control group (M = 2.84; SD = 0.66) than in the target group (M = 2.47; SD = 0.89).

Discussion: The results indicate that VT in forensic practitioners does not emerge as a clinically relevant condition but rather as cognitive restructuring. The limited variability within the group suggests a shared adaptation centered on emotional detachment. Participants reported moderate emotional distress and greater reliance on defense mechanisms, pointing to a mediating role of training and supervision. Interestingly, the control group showed even higher distress levels despite no trauma exposure, with similar cognitive changes, suggesting that psychosocial vulnerabilities can mirror VT. Thus, VT effects may be amplified by personal history, influencing overall well-being. The variability of protective resources, mainly individual, highlights the need for structured preventive and supportive strategies.

Conclusion: VT in forensic professionals primarily impacts the cognitive sphere, altering meaning-making mechanisms rather than producing true psychopathology. These findings support cognitive models of VT and emphasize the need for organizational support and structured supervision to mitigate risk and sustain professional functioning.

DD2 When Cases Fuel and Fracture: Unraveling the Mental Health Paradox in Forensic Science

Donia Slack, PhD, Nova Southeastern University, Holly Springs, NC*

Learning Objectives: Attendees will understand how traumatic case exposure specifically impacts work performance and mental health outcomes in forensic science personnel. Participants will gain knowledge of the prevalence of Vicarious Trauma (VT) and burnout in the forensic workforce and learn about validated assessment methodologies used to measure these conditions. Upon completion, attendees will be able to recognize the correlation between traumatic case exposure and decreased work ability while understanding the paradoxical relationship between engagement and trauma exposure in forensic professionals.

Impact Statement: This presentation will enhance the forensic science community's competence in recognizing and addressing mental health challenges that directly affect laboratory performance and case outcomes. The findings demonstrate that VT significantly impacts forensic scientists' perceived ability to perform their duties, with implications for quality assurance, error rates, and the fair administration of justice. Understanding these relationships will enable laboratory managers and administrators to implement targeted interventions that protect both personnel well-being and operational effectiveness.

Abstract Text: This study examined the prevalence of VT and burnout among forensic science practitioners and their impact on work ability using a causal-comparative quantitative research design with 585 participants. The research addressed two critical questions: whether forensic scientists experience VT and burnout due to traumatic case exposure, and whether these conditions affect their perceived job performance capabilities.

Participants completed validated instruments including the Trauma and Attachment Belief Scale (TABS), Oldenburg Burnout Inventory (OLBI), Case Exposure Scale (CES), and Work Ability Index (WAI). The sample comprised 77.1% female participants, with 61.2% having 4-20 years of forensic science experience across disciplines including crime scene investigation, DNA analysis, toxicology, and pattern evidence examination.

Results revealed that 83% of participants exhibited average to extremely high levels of VT, significantly higher than the general population. A statistically significant positive correlation ($r = 0.09$, $p < 0.05$) was found between traumatic case exposure and VT development.[1] Regarding burnout, 27.9% exhibited moderate total burnout, with 34.5% showing moderate exhaustion levels. Surprisingly, increased traumatic case exposure correlated with decreased disengagement and exhaustion ($r = -0.09$, $p < 0.05$), suggesting that forensic scientists find greater engagement and fulfillment when working serious cases.[2]

Critical findings emerged regarding work ability: VT showed a significant negative correlation with perceived work ability ($r = -0.35$, $p < 0.01$), with VT predicting 12% of work performance variance. Conversely, burnout showed a positive correlation with perceived work ability ($r = 0.47$, $p < 0.01$), predicting 22% of performance variance, indicating that burned-out forensic scientists paradoxically maintain confidence in their job performance capabilities.[3]

The study demonstrates that forensic scientists frequently encounter traumatic material, leading to measurable psychological impacts that affect their perceived ability to perform essential duties. While traumatic case exposure increases engagement, it simultaneously develops VT that negatively impacts work capacity through increased illness-related absences and reduced effectiveness.[4] These findings have significant implications for laboratory management, quality assurance protocols, and the broader criminal justice system.

The research highlights the need for targeted mental health interventions, workload distribution strategies, and organizational support systems to maintain workforce resilience while preserving the engagement that drives forensic professionals' commitment to justice. Understanding these relationships is crucial for maintaining laboratory effectiveness and ensuring reliable forensic science outcomes in criminal proceedings.

DD3 Mental Health and the Effects of Mass Fatality Response: The COVID-19 Response in New York City

Justin Z. Goldstein, PhD, NYC Office of Chief Medical Examiner, New York City, NY; Helen S. Alesbury, MA*, NYC Office of Chief Medical Examiner, New York City, NY*

Learning Objectives: After attending this presentation, attendees will have a greater understanding of the impacts that responding to COVID-19 had on medical examiner personnel in New York City.

Impact Statement: This presentation will impact the forensic science community by providing critical data on how mass fatality response influences practitioner mental health over time through longitudinal survey data.

Abstract Text: Vicarious Trauma (VT) is the secondary traumatization of individuals who interact with others who are experiencing a trauma or crisis. Medical examiner personnel are regularly exposed to VT in their daily activities, not only when conducting casework but also when interacting with families and communities of the deceased. During mass fatality events, these demands increase and occupational interactions may intensify, potentially impacting practitioner wellness. While substantial literature exists regarding the impacts of VT on first responders, fewer studies have addressed the wellness needs of medical examiner staff.[1-3] Moreover, no studies have addressed the longitudinal impact of VT in relation to medical examiner mass fatality response. To address this deficit, this research presents quantitative and qualitative data from longitudinal surveys at the New York City Office of Chief Medical Examiner (NYC OCME) from 2019-2023, reporting how non-clinical measures of practitioner wellness changed over time in relation to COVID-19 response.

Four anonymous online surveys were sent to all NYC OCME staff (IRB exemption from NYC Department of Health and Mental Hygiene). Surveys were deployed in 2019, 2020, 2021, and 2023. All surveys included questions about participant demographics, education level, professional experience, department of employment, overtime hours worked, and participant experience responding to mass fatality incidents. Participants were also asked to quantitatively self-report perceived levels of stress, support, happiness, satisfaction, pride, investment, comfort, and burnout. In addition, participants were able to share experiences, comments, and concerns in open-ended formats. Collectively, this approach allowed for both quantitative and qualitative data collection over a four-year study period. Responses were aggregated and analyzed in IBM SPSS (quantitative data) and NVivo 15 software (qualitative data).

In total, 487 responses were collected from 2019-2023. Most respondents were employed in laboratory settings such as Forensic Biology, Forensic Toxicology, and Forensic Histology (n=167). Other well-represented departments included Mortuary (n=70), Administration (n=59), Medicolegal Investigations (n=58), and Forensic Pathology, including Anthropology (n=56).

Results indicate no significant changes in self-reported stress or self-perceived support between the 2019-2023 surveys, emphasizing the idiosyncratic nature of stress and support. Self-reported burnout levels increase from 2019-2021 and decrease from 2021-2023. A similar decrease is observed between weekly overtime hours worked in this timeframe, possibly contributing to the observed burnout decrease.

Word similarity cluster analysis indicates that the open-ended response language for the 2020-2023 surveys cluster together with strong correlations (r = 0.72-0.78) compared to 2019 which plots separately and exhibits weaker correlations (r = 0.44-0.50). Response sentiment coding supports this finding, showing a shift in positive and negative sentiment intensity between 2019 and 2020. These qualitative results provide insight into the impacts of COVID-19 response on NYC OCME staff and the value of incorporating qualitative analyses in wellness research.

Collectively, quantitative and qualitative results speak to a change in practitioner wellbeing in relation to mass fatality response. This research provides a critical perspective into practitioner experiences before, during, and after mass fatality response that can help identify practical strategies for the future development of wellness resources and infrastructure that meets the needs of medical examiner personnel.

LS2 Disaster Management for the Forensic Laboratory: A Hurricane Katrina Primer and Retrospective

Anna S. Duggar, PhD, Loyola University New Orleans, New Orleans, LA*

Learning Objectives: This session will explore the fundamental roles, responsibilities, and needs of forensic laboratories after a disaster, using Hurricane Katrina in New Orleans as a case study. Key points of discussion will include: impacts on laboratories during a natural disaster; changing demands on the laboratory and on individual analysts during the immediate response and subsequent recovery; and the ways in which standard disaster preparation and response guidelines may not take into account the particular needs of forensic laboratories. Concerns of physical plant, personnel, evidence, and the long-term potential for assistance and recovery will be discussed, as well as opportunities to be found at the center of the crisis.

Impact Statement: This presentation will impact the forensic science community by highlighting the benefits of basic disaster preparedness, specifically tailored to the forensic laboratory. Attendees will gain a deeper understanding of the strengths and vulnerabilities of their labs, learn from real-world experiences, and leave the presentation with a foundation for short-term and long-term efforts to prepare for simultaneous response and recovery from natural disasters in future.

Abstract Text: Twenty years ago, in August 2005, Hurricane Katrina made landfall along the Gulf Coast. In the morning hours of August 29, 2005, federal levees in New Orleans failed. The city, vulnerable due to its geographic position below sea level, experienced extreme flooding that caused unprecedented destruction of life and property.

The New Orleans Police Department was decimated: communication systems failed, and vehicles, buildings, and other essential equipment became unusable. Vital infrastructure was damaged, including the Crime Lab and Central Evidence and Property, both submerged under feet of water full of urban contaminants. As a result, forensic operations were severely disrupted for months, and the status of every item of evidence in the municipal system left uncertain.

We in the forensic community, informed by extensive scholarly analysis from past events, are increasingly well-equipped to respond to high-profile mass disasters. We are less prepared for the challenges of being a casualty of the disaster. This presentation will detail the experiences of the NOPD Crime Lab during and after Hurricane Katrina, presenting direct impacts of the storm and the process of recovery. By focusing both on individual contributions and on collaborative efforts, the presentation will use a retrospective systems approach to encourage attendees to begin considering how their laboratories can approach simultaneous response and recovery during future natural disasters.

Hurricane; Mass Disaster; Laboratory Infrastructure

LS3 Grizzlies, Guns, and Glaciers: Interesting National Park Deaths

Tatiana Bihun, MD, Saint Louis City Medical Examiner's Office, St. Louis, MO*

Learning Objectives: National Parks fall under various jurisdictions, to include Federal, Local and Reservation. These different landscapes not only include glaciers, large bodies of water, forests, mountains, caves and deserts, but also encompass all four seasons. Attendees will learn of the complex nuances needed to complete investigations and hear interesting cases that are unique to our National Parks.

Impact Statement: Presenting on National Park deaths will impact the forensic science community by highlighting not only the intricacies of interjurisdictional collaboration to include local police, tribal police, National Park Rangers, coroner offices, and medical examiners offices, but also the challenges of completing death investigations in the absence of a body. It highlights the differences of resources, training, environment, and types of visitors that is unique to each National Park.

Abstract Text: National Parks, located in the United States, are visited by over 300 million people a year. From 2014–2019, a total of 2,149 deaths were recorded. Despite deaths drawing media attention, the parks are relatively safe. Mortality data, collected by the National Park Service, reported a mortality rate of 0.11 per 100,000 recreational visits, substantially lower than the 715 deaths per 100,000 people of the overall United States population. Death investigations that take place in our National Parks cover a multitude of breathtakingly beautiful yet harsh terrains. There are even cases in which that the topography is so harsh that bodies are not recovered and individuals are "presumed" dead. National Park investigations are also complex in the sense that they often cross not only multiple states, but multiple jurisdictions.

We present multiple cases from our National Parks from Denali National Park in Alaska to Gateway National Park in Missouri. Deaths resulted from multiple different causes, including but not limited to: environmental exposure, accidental firearm discharge, animal attack, airplane crashes, and falls. Cases were shared by coronary, death investigators and medical examiners. Manner of Death was determined by not only autopsy examination, but from thorough scene investigation by either National Park Rangers or other death investigators, also including the police. These cases also highlight the principle of "presumed dead" and the challenges of body recovery in the setting of rough terrain.

LS4 Deriving Forensic Intelligence Using Artificial Intelligence

Vinicius Lima, PhD, SUNY Albany, Lafayette, IN*

Learning Objectives: In this talk, the audience will explore the history of forensic intelligence, its application within forensic Science, and the current and future challenges involved in its practical implementation. We will then discuss how Artificial Intelligence (AI) technologies can support and enhance forensic investigations. This section will also address the limitations and challenges AI faces when applied to forensic contexts. A practical example will be presented to illustrate how AI techniques, particularly those based on Natural Language Processing (NLP) and simple analytical visualization tools, can be leveraged to extract insights from forensic evidence. It will be shown how such work generates insights, including uncovering crime patterns, supporting case linkage analysis, and informing public security policies. The goal of this talk is to introduce the audience to the intersection of forensic intelligence and AI and to foster discussion among interested participants for future contributions in the field.

Impact Statement: By gaining a deeper understanding of the forensic intelligence landscape and the potential of AI to enhance the field, the audience will be better equipped to expand their knowledge, engage in meaningful discussions, and contribute to future research and innovation in this emerging area.

Abstract Text: Forensic intelligence represents a shift from the traditional case-by-case approach in forensic science to a more holistic, macro-level analysis of evidence, one that aims to generate intelligent criminal and forensic insights. Although widely discussed in the literature, real-world implementation remains limited, often facing significant operational and institutional barriers. This seminar will explore these challenges and examine why practical adoption has proven difficult.

Similarly, AI is transforming many fields, including forensic science. We will discuss how AI can enhance forensic intelligence by uncovering criminal behavior patterns, supporting case linkage, and informing public safety strategies. In particular, we will explore how NLP techniques can be applied to existing police and forensic artifacts to generate actionable insights. We will also address the unique challenges AI faces in forensic contexts, including issues of data quality, model interpretability, and legal admissibility.

To ground the discussion in practice, the seminar will feature a case study using crime scene report data from a police institution in Brazil. This example will demonstrate how AI tools can extract high-level insights from forensic narratives to support evidence-based decision-making in public safety.

The seminar aims to foster an open dialog on the integration of forensic intelligence and AI. As will be discussed, advancing this field requires collaboration among all relevant stakeholders, including forensic scientists, researchers, criminal justice professionals, and government agencies.

LS5 Failure to Do the Fundamentals: The Forensic Investigation of the *Titan* Submersible and OceanGate

Bart B. Kemper, PE, Kemper Engineering Services, Baton Rouge, LA*

Learning Objectives: The 2023 loss of the *Titan* submersible and the five fatalities off the coast of Halifax captured the world's attention. The U.S. Coast Guard and National Transportation Safety Board conducted a joint investigation, with the October 2024 Marine Board of Investigation bringing to light many issues regarding CEO Stockton Rush and the OceanGate team. This presentation will provide insight into the information presented during the eight days of testimony.

Impact Statement: Attendees will gain knowledge of the sequence of events of the investigation into OceanGate and the *Titan* submersible implosion. There will be a focus on the Verification, Validation, and Uncertainty Quantification (VVUQ) process, its role in innovation, and how VVUQ is part of the due diligence for applying engineering simulations, including in a forensic investigation. Finally, attendees will gain insight into how to form a successful multidisciplinary team to confront a novel forensic situation.

Abstract Text: OceanGate was seen by many as a revolutionary leader in underwater exploration. They were profiled in publications like the *Smithsonian* and *Fast Company*. In June 2023, OceanGate took their flagship submersible, *Titan*, on its last expedition to the wreck of the HMS *TITANIC*. On June 18, 2023, the company CEO, Stockton Rush, took four people aboard the *Titan* and descended into the Atlantic. About 90 minutes later, the submersible imploded, killing everyone aboard. The presenter, Bart Kemper, was one of the professionals who signed a letter to OceanGate warning them of industry concern regarding the safety of OceanGate's operations. Kemper is a consulting engineer and a member of the codes and standards committee for Pressure Vessels for Human Occupancy, the engineering code for non-military submarines as well as other pressurized applications such as hyperbaric medical systems, commercial diving, and pressurized tunnel boring machines. He is also an Academy member of the Engineering and Applied Science section and was the Editor-in-Chief of the *Journal of the National Academy of Forensic Engineers*. In early 2024, he was asked by the joint National Transportation Safety Board (NTSB) and US Coast Guard (USCG) investigation to review the information recovered from OceanGate and provide an engineering assessment. Using investigation into the *Challenger* shuttle disaster as a model, Kemper formed a 13-person team to provide a comprehensive multidisciplinary review. This presentation will focus on the forensic procedural aspect of the investigation and the primary findings. As of the time of submission, the results of the investigation are not scheduled to be released as of the time of the conference. The information will be constrained to what was placed into public knowledge by the MBI and various documentaries.

Failure Analysis; Ethics; Mass Fatality

LS6 Postmortem Computed Tomography (PMCT) Basics and Beyond: A Game of Jeopardy for Strong Stomachs

Jamie M. Elifritz, MD, Forensic Radiology Group, Destin, FL*

Learning Objectives: This presentation will: (1) introduce fundamental PMCT findings, including pattern recognition; (2) demonstrate the PMCT findings of frequently encountered pathology; (3) strengthen understanding of PMCT basic concepts through engaging case-based examples that integrate radiologic-pathologic correlation; and (4) foster critical thinking in the evaluation of complex and atypical PMCT cases.

Impact Statement: This interactive seminar bridges foundational principles with modern imaging technology in a format that is both educational and memorable. By combining case-based learning, peer-reviewed imaging examples, and live audience participation, the session reinforces critical PMCT concepts while emphasizing the responsible application of PMCT in medicolegal death investigations. Attendees will leave with a stronger grasp of PMCT fundamentals, enhanced diagnostic confidence, and a renewed appreciation for collaboration between forensic pathologists and radiologists. .

Abstract Text: Join us for an exciting game of PMCT Jeopardy—a high-energy, interactive luncheon seminar that blends the fundamentals of PMCT with some fascinating and bizarre cases. We will explore cases ranging from hemopericardium to things that make you say, "Hmm." In line with the AAFS 2026 theme, *Back to Basics: The Fundamentals of Forensic Science,* this session reinforces core principles in PMCT while embracing the power of storytelling and shared expertise.

Luncheon participants will split into two competing teams (one side of the room vs. the other) to test their knowledge in categories such as *Classic PMCT Findings*, *Affairs of the Hear*t, and *You Might Lose Your Lunc*h. Real cases from daily practice, ranging from textbook examples to head-scratching surprises, will be presented alongside brief teaching points (and some provocative stories), all backed by current best practices.

Whether you're new to PMCT or a seasoned forensic professional, this fun and fast-paced game will leave you with new insights, a few laughs, and maybe even a cool prize for your team. Expect plenty of participation, a bit of dark humor, and a reminder of why sound fundamentals and critical thinking remain the backbone of forensic science.

W1 Back to Basics: Foundations of Medicolegal Death Investigation

Kathleen Diebold Hargrave, MA, Office of the Regional Medical Examiner, St. Charles, MO; Erin Worrell, BSc*, Franklin County Forensic Science Center, Columbus, OH; Michelle Rippy, EdD*, California State University East Bay, Hayward, CA; Kelly Allmeyer, BA*, Regional Medical Examiner Serving the Counties of Franklin, Jefferson and St. Charles, Defiance, MO; Lisa A. Potteiger-Visconti, BS*, Harrisburg, PA; Tara Rick, BA*, St. Louis City Medical Examiner's Office, St. Louis, MO; Alisha M. Simpson, MS*, Dauphin County Coroner Office, Paxinos, PA*

Learning Objectives: By the end of this workshop, attendees will be able to identify the basic and core responsibilities of medicolegal death investigators, including next-of-kin notifications, scene documentation, and report writing. Attendees will analyze investigative strategies for child deaths, drug-related fatalities, cold case management, and mass fatality response using current national standards. They will demonstrate understanding of interdisciplinary collaboration and apply lessons learned from real case examples to improve investigative accuracy and scene outcomes.

Impact Statement: This workshop provides foundational training in medicolegal death investigation, covering next-of-kin notification, scene photography, infant and drug deaths, cold cases, report writing, and mass fatality response. Attendees will learn to apply investigative advancements and national standards, improving documentation, scene outcomes, and multidisciplinary collaboration in complex cases.

Abstract Text: Are you looking to sharpen your skills in medicolegal death investigation, gain confidence in complex casework, and strengthen your ability to serve your community through thorough medicolegal investigations? This full-day workshop, Back to the Basics: Foundations of Medicolegal Death Investigation, is designed to meet the evolving needs of medicolegal death investigators, whether you're new to the field or seeking a refresher grounded in today's challenges and standards. Participants will receive practical, scenario-based instruction on core responsibilities, including Next-Of-Kin (NOK) notification, scene photography, and effective report writing. You'll gain insight into specialized areas such as child death investigation, drug-related fatalities, long-term unidentified cases, and mass fatality response. Real-world case studies will illustrate common pitfalls and key takeaways, allowing attendees to connect protocols with practical applications. A highlight of the workshop includes a dedicated session on mass fatality response. The presenter brings firsthand experience managing high-profile mass fatalities. The presenter will walk attendees through the complexities of interagency coordination, victim identification, and logistical operations during mass fatality events. Her insights are grounded in real cases she has handled, including the 2013 plane crash at San Francisco International Airport and a tragic limousine fire that claimed the lives of five nurses trapped inside. This session offers valuable, practical guidance for investigators tasked with navigating the chaos, scale, and sensitivity of mass fatality incidents—skills that are increasingly vital in our changing public health landscape. The afternoon will feature interactive, co-presented case reviews showcasing unique and notable investigations. These real cases, presented by seasoned professionals, will demonstrate investigative strategies, lessons learned, and the integration of advancement such as professional certification via the American Board Medicolegal Death Investigators (ABMDI), Sudden Unexpected Infant Death Investigation protocols (SUIDI protocols), digital documentation and Forensic Investigative Genetic Genealogy (FIGG). These presentations are designed to spark peer discussion and provide immediate applicable tools and insight. A panel discussion will close the session, giving attendees a chance to ask questions, share perspectives, and explore emerging issues such as unclaimed remains, workforce burnout, and ethical scene response. Participants will also receive digital handouts, reference materials, including ASB Published standards to support their ongoing professional development. If you're ready to build confidence, improve scene investigations, and align your practices with national standards—all while learning from experienced medicolegal death investigators—this interactive workshop will deliver the knowledge, tools, and connection you need to strengthen your investigative work and better serve the communities that depend on it.

W2 Intimate Partner Homicide: How to Detect, Investigate, and Prevent Misdiagnosis

Andrea Zaferes, MFS, Dutchess County Medical Examiner's Office/FACT, Shokan, NY; Joni E. Johnston, PsyD*, Del Mar, CA; Paul S. Uribe, MD*, Fort Bend County Medical Examiner Office, Richmond, TX; Kristen E.L. Edwards-Bova, BS*, Larimer County Coroner's Office, Fort Collins, CO; Micaela A. Ascolese, MS*, RTI International, Durham, NC; Kelsey McKay, JD*, Law Firm of Kelsey McKay, Austin, TX; Jan M. Gorniak, DO*, World Peace Forensic Consulting, LLC, Tallahassee, FL; James K. Roberts, APM*, Bingham County Coroner's Office, Blackfoot, ID; Kiersten Reif, BA*, Bannockburn Police Department, Bannockburn, IL; Kenneth Rosgen*, Polk County Medical Examiner's Office, Dallas, OR*

Learning Objectives: This workshop addresses Intimate Partner Staged Homicides (IPHs) and teaches participants how to recognize, document, investigate, and prosecute IPHs by reinforcing foundational investigative practices and incorporating "new basics" consisting of validated investigation tools. Through case scenarios and subject matter experts, participants will demonstrate the ability to recognize IPH indicators and implement at least three response strategies and four tools that can help triage cases for the need for search warrants, scene processing, autopsies, etc. Attendees will be able to explain at least three types of bias that have contributed to cases being missed and misdiagnosed by all levels of practitioners. Each stage of the process will emphasize the need for a multidisciplinary approach from medicolegal death investigators, forensic pathologists, law enforcement, and prosecutors.

Impact Statement: Globally, more than 50% of femicides are committed by current or ex-IPs.[1] In some of these cases, offenders will conceal homicides by disguising them as non-suspicious deaths (i.e., natural, accident, or suicide) or missing person cases, causing misdirection, and impacting case resolution and prosecution. In response to these IPHs, and as many agencies are overwhelmed with cases and underfunded, there is a greater need for validated decision-making and investigation tools. This workshop will: (1) provide crucial background information and training on what IPHs are and how to identify them; (2) when and how to respond to them; and (3) ultimately support more accurate determinations of cause and manner of death, leading to improved justice outcomes for victims and their families.

Abstract Text: IPHs remain among the most frequently misdiagnosed and overlooked types of death, often due to persistent gaps in investigative practices. This presentation challenges all professionals—from patrol officers and Medicolegal Death Investigators (MDIs) to Forensic Pathologists (FPs) and prosecutors—to return to foundational investigative principles: asking critical questions, avoiding premature conclusions, and remaining open to all possible manners of death, regardless of dispatcher narratives or reporting party accounts. Simultaneously, this session introduces "new basics," including contemporary knowledge about offender staging tactics, coercive control, and validated tools of lethality risk indicators that precede IPH. Offenders may stage deaths to resemble accidents, suicides, or natural causes—sometimes crafting these false narratives over the course of months or years. Traditional reliance on fatal anatomical findings such as ligature marks, neck hemorrhage, or blunt force trauma can be insufficient. There may be no findings of fatal injuries on IPH victims when they are first incapacitated by asphyxiation or toxicology or are behaviorally compliant to being assaulted. Of particular concern is strangulation, a well-documented predictor of future IPH, and which, externally, is more easily missed for victims with dark skin tones. Autopsy findings can determine a defect to be a contact Gunshot Wound (GSW), but they cannot determine who pulled the trigger. Likewise, they cannot determine who created alleged hanging ligature marks, who caused the fatal overdose, or how a boat overturned. And causes of death such as drowning are determined by diagnoses of exclusion and circumstances. This presentation emphasizes the need to look beyond what can be seen on autopsy and instead consider behavioral, historical, and contextual evidence that may better reveal the presence of abuse, risk, and homicide indicators. Cognitive and several other types of bias will also be addressed as major barriers to effective investigations, and accurate cause and manner of death determinations and opinions, respectively. This session will explore how such biases can interfere with objective evaluation, and how structured decision-making tools can help counteract them. Arguments on overcoming bias will be presented, for example, showing why FPs should consider corroborated circumstances in conjunction with autopsy findings, and how validated tools and best practices can be used by both Medicolegal Death Investigators (MDIs) and law enforcement to help determine what cases to accept for autopsy and to know when detectives and scene investigators should be dispatched, respectively. Participants will examine real-world cases of missed and misdiagnosed IPHs and will be trained to apply validated tools such as the Danger Assessment (DA), Joanna's Law Criteria, and the Monckton Smith IPV Homicide Timeline. Emphasis will be placed on early intervention, pre-autopsy scene assessment, and multidisciplinary collaboration. Resources such as experts in ligature-system analysis, toxicology, aquatic death investigation, and Intimate Partner Violence (IPV) advocacy will be highlighted to encourage holistic, evidence-informed investigation. By reinforcing both foundational and emerging investigative practices—and by fostering professional environments that empower practitioners to challenge prevailing narratives—this session aims to reduce missed and misclassified IPHs, ensure accurate cause and manner of death determinations, and promote justice for victims.

W3 Pediatric Neuropathology in Forensic Practice

Jolee Suddock, DO, Office of the Chief Medical Examiner, Oklahoma City, OK; Melissa M. Blessing, DO*, Johnson County Medical Examiner and University of Iowa Health Care, Iowa City, IA; Rebecca D. Folkerth, MD*, MooseHenge Medical Consulting, High Falls, NY; Jared T. Ahrendsen, MD, PhD*, Northwestern University Feinberg School of Medicine, Chicago, IL; Michael Harrell, MD*, Office of the Chief Medical Examiner, Oklahoma City, OK; Lorraina J. Robinson, DO*, University of Oklahoma, Oklahoma City, OK*

Learning Objectives: Through collaborative insights from multiple experts in the field, attendees will gain practical knowledge and diagnostic strategies related to perinatal and pediatric neuropathology, applicable to forensic autopsy examination in all age groups. Learning objectives included in this talk include the following: (1) understand and describe developmental and acquired neuropathology resulting in immediate or delayed death; (2) describe neuropathologic evaluation in seizure disorders, trauma, and the utility of ancillary stains for microscopic examination; and (3) summarize the role of advanced diagnostic tools, including molecular testing and postmortem imaging, and assess their practical utility and limitations in the forensic evaluation of pediatric and perinatal deaths.

Impact Statement: This knowledge will impact the forensic science community by enhancing the understanding of developmental neuropathology, sample collection, diagnostic criteria, and interpretation of common neuropathologic findings in perinatal and pediatric autopsies that can also be implicated as a cause of death in later age groups. By fostering a comprehensive and systematic approach, the session aims to advance the field of forensic neuropathology and support multidisciplinary collaboration.

Abstract Text: This immersive half-day workshop provides a comprehensive introduction to pediatric and perinatal forensic neuropathology, emphasizing core skills applicable to forensic pathologists regardless of prior neuropathology experience. Designed to reinforce diagnostic fundamentals, the session focuses on recognizing normal and abnormal brain development, selecting appropriate tissue sections, and interpreting key neuropathologic findings in infants and children. Participants will learn to distinguish age-appropriate neuroanatomic structures from developmental anomalies and will be guided on when to preserve the brain for deferred examination versus when to sample *in situ*. Fixation techniques, dissection strategies, and tissue selection protocols will be covered in detail, with an emphasis on practical application in busy forensic settings. Instructional modules will include normal and abnormal neurodevelopment, common findings in acquired conditions such as epilepsy, and forensic evaluation of pediatric trauma, including both inflicted and accidental injuries. Emphasis will be placed on common pitfalls, effective documentation, and integrating findings into clear, defensible cause-of-death determinations, including sudden death in infants and children (SUID/SUDC). The workshop will also feature real-world cases, high-yield histologic and gross images, and practical handouts to support long-term retention and on-the-job reference. With a case-based, interactive approach and expert instruction, participants will gain confidence and a systematic framework for pediatric neuropathologic evaluation in forensic autopsy practice.

Autopsy; Neuropathology; Pediatric

W4 Fundamentals of Blast, Blast Effects, and Forensic Investigations

Bart B. Kemper, PE, Kemper Engineering Services, Baton Rouge, LA; Krista Wohlfeil*, Kemper Engineering Services, Baton Rouge, LA; William Sayin, BSME*, Booz Allen and Hamilton, Baton Rouge, LA; Paul Messner, JD*, FBI, Dry Ridge, KY*

Learning Objectives: Attendees of this workshop will learn about different types of blast, the type of damage and injuries blast can cause ("blast effects"), and how to apply the information as key elements of investigating a blast event.

Impact Statement: This workshop will impact the forensic science community's practice by introducing foundational concepts regarding blast and blast effects in order to provide a framework for a better understanding of forensic investigations involving blast and blast effects.

Abstract Text: This workshop will introduce the engineering and medical concepts of what a blast event is and how an accidental, industrial, criminal, military, and terroristic event can differ. Blast is more than "a big boom" and it's far from just a military or terrorist issue. The United States Bomb Data Center (USBDC) identified a total of 770 explosions reported in their Bomb Arson Tracking System (BATS) and the Technical Resource for Incident Prevention (TRIPwire). Of these explosions, 320 were identified as bombings. Separately, data collected by the Pipeline and Hazardous Materials Safety Administration (PHMSA) indicates 23 fatalities in 2023 due to gas-related home explosions. The National Fire Protection Association (NFPA) identified 18 large-loss fires and explosions with property damage of at least $10 million. This workshop will give the attendees more context regarding these different types of events in order to better support detailed investigation. If you don't know what you are looking for, you won't know it when you see it. The overall investigation field goes beyond explosions. It includes recoveries, suspicious packages, bomb threats, hoaxes, and explosives thefts/losses, with a total of 18,088 such incidents reported in 2023. Often a chronic safety issue or a violent murderer can be detected, investigated, and appropriately mitigated. Early recognition of explosive hazards can be key in preventing a catastrophic event. This workshop will be at an introductory level for forensic professionals. First, the term "Explosive Hazards" will be explained, ranging from battlefield Improvised Explosive Devices (IEDs) to gas mains and medical gases. Commercial blasting is mentioned but will be omitted. Secondly, the anatomy of a blast wave will be presented, including the difference between high- and low-explosives and how they are used. Third, the different effects will be discussed, including hazards from fragments and projectiles. Finally, the workshop builds upon the previous information to discuss the different forensic methods and tools available. These tools include commercial and governmental blast modeling programs as well as more conventional engineering programs. Participants will gain experience during the break by using their knowledge to evaluate items brought as a "petting zoo" where case information and post-blast items are discussed in small groups. These items include fragments from IEDs; a before-and-after for an Explosively Formed Projectile (EFP); bullets that were defeated by different types of armor; and case summaries with photos marked to encourage discussion. This class will not be providing information on how to construct an IED or timing device, nor will it discuss damage due to ground shock from construction or quarrying explosives.

Explosion; Injury; Forensic Investigation

W5 Back to Mass Spectrometry Basics: Analysis and Spectral Interpretation

Sandra E. Rodriguez-Cruz, PhD, DEA Special Testing and Research Laboratory, Dulles, VA; Matthew R. Wood, PhD*, Ocean County Sheriff's Office, Toms River, NJ*

Learning Objectives: During this workshop, attendees will learn the fundamental principles of mass spectrometry and spectral interpretation. This will include an understanding of the main components of the mass spectrometer, ionization, separation, and detection. The attendees will learn techniques for small molecule structure elucidation such as identification of the molecular ion, elemental composition, and the analysis of basic fragmentation patterns.

Impact Statement: This workshop will impact the forensic science community by providing an educational opportunity for new forensic scientists to expand their understanding of mass spectrometry and offer a refresher course for more seasoned chemists. The goals of this workshop are to increase the attendees' working knowledge of the mass spectrometer while improving their ability to recognize and interpret mass spectra, thereby increasing their confidence in compound identification.

Abstract Text: Mass spectrometry is the most widely used and accepted technique for identifying controlled substances and their metabolites in seized drug analysis and toxicology laboratories worldwide. Its high sensitivity and specificity make it indispensable in forensic science, enabling the accurate detection and quantification of a wide range of analytes. As part of the "Back to Mass Spectrometry Basics" theme, this workshop will introduce the core principles of mass spectrometry, provide a detailed overview of structure elucidation techniques, and highlight the interpretation of mass spectra in the identification of Novel Psychoactive Substances (NPS). The workshop will begin with an overview of the fundamental components of a mass spectrometer. Participants will learn how ions are generated in the ion source, separated by their mass-to-charge ratio (m/z) in the mass analyzer, and detected and recorded by the detector. Emphasis will be placed on how these components work together to generate a mass spectrum and how variations in instrumentation and method parameters can influence analytical results. The focus will then shift to the use of Electron Ionization/Mass Spectrometry (EI/MS) for chemical structure elucidation. Key topics will include the interpretation of molecular ions and base peaks, as well as the distinction between atomic, nominal, average, and accurate mass. Essential principles such as isotopic distributions, the nitrogen rule, and the calculation of rings plus double bonds (r + db) to determine elemental composition will be covered in detail. Participants will learn common EI/MS fragmentation mechanisms, including sigma and alpha cleavages, inductive effects, neutral losses, and charge retention versus charge migration events, all while gaining a better understanding of how odd-electron and even-electron ions behave. Afternoon sessions will reinforce these concepts through interactive, hands-on exercises and problem-solving scenarios. Real-world structure elucidation examples involving novel psychoactive substances will be used to apply theory to practice. The workshop will conclude with a discussion of spectral libraries, interpretation tools, and an overview of other complementary mass spectrometric techniques that can enhance compound identification in forensic casework such as Electrospray Ionization–Mass Spectrometry (ESI-MS) and Direct Analysis in Real Time-Mass Spectrometry (DART-MS).

Mass Spectrometry; Interpretation; Seized Drugs

W6 Ketamine: The Clinical Renaissance and Traffic Safety Implications

Nicholas B. Tiscione, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL; Corina Freitas, MD*, Freitas and Associates LLC, Alexandria, VA; Svante Vikingsson, PhD*, RTI International, Research Triangle Park, NC; Edward X. Zumaeta, MS*, Palm Beach County Sheriff's Office, West Palm Beach, FL; Rebecca L. Hartman, PhD*, Monroe County Office of the Medical Examiner, Rochester, NY; Samuel Wilkinson, MD*, Yale School of Medicine, Yale Depression Research Program, New Haven, CT*

Learning Objectives: Attendees will gain an understanding of the reason for the recent surge of interest in ketamine for promising new clinical applications and potential for misuse. Participants will: (1) become familiar with the increased research and prevalence of ketamine in the United States; (2) understand the basic pharmacology of ketamine; (3) gain insight into the most recent clinical research, appropriate use, and potential risks of ketamine; (4) appreciate the implications of side effects to human performance; and (5) recognize the presentation of impairment of normal faculties in subjects consistent with ketamine use and the impact to traffic safety.

Impact Statement: An impact to the forensic science community will be accomplished by increasing attendees' understanding of the clinical applications and potential adverse effects of ketamine. As the use of ketamine has increased significantly in the past ten years, practitioners will be better prepared to recognize both the beneficial effects and adverse events that it may produce.

Abstract Text: Ketamine has been in clinical use since the 1960s as a general anesthetic. The past ten years have marked a period of vigorous research activity into new clinical applications for ketamine. This includes low-dose administration in concert with therapy for treatment-resistant depression, pain management, and addiction. Along with this period of increased academic research and clinical use has come a corresponding growth in public interest and recreational use. Over the past decade, the number of ketamine drug possession cases submitted to crime laboratories in the United States has increased by three-fold. Recent illicit preparations include "pink cocaine," most commonly a mixture of ketamine and Methylenedioxymethamphetamine (MDMA). The basics of ketamine will be introduced, from its development and continued primary use as a general anesthetic to the recent clinical applications for low-dose administration. Current understanding on the pharmacodynamics and pharmacokinetics will be discussed to frame the scope of effects and their duration while recognizing the remaining knowledge gaps on its mechanisms of action. An objective overview of the benefits and risks of ketamine use will conclude with the implication for traffic and other safety concerns discussed through a presentation of authentic cases. Get back to basics and advance your knowledge with a first-hand instruction on the bedrock scientific research by a leader in the field and Medical Director of the Yale Depression Research Program. This is a Society of Forensic Toxicologists/American Academy of Forensic Sciences (SOFT/AAFS) Drugs and Driving Committee-sponsored workshop.

Ketamine; Clinical Research; Impaired Driving

W8 A Multiagency Response to the Mid-Air Collision: A Strategic Approach and Lessons Learned

Jennifer C. Love, PhD, DC DFS, Washington, DC; Micayla Spiros, PhD*, DC Office of the Chief Medical Examiner, Washington, DC; Francisco C. Diaz, MD*, Office of the Medical Examiner/DC Department of Forensic Sciences, Washington, DC; Daniel Morgan, MFS*, National Transportation Safety Board, Washington, DC; Lalynn G. Kurash, M*S, DC Office of the Chief Medical Examiner, Washington, DC; Katherine Hyun Kim, MS*, DC Office of the Chief Medical Examiner, Washington, DC; Krystyna Hopkinson, MSFS*, DC Department of Forensic Sciences, Washington, DC; Julie Ferragut, BS*, DC Department of Forensic Sciences, Washington, DC; Sara Achrati, MD*, DC Office of the Chief Medical Examiner, Washington, DC; Mike Cariola, MF*S, Bode Technology, Lorton, VA; Carley Chwal, MSFS, Bode Technology, Lorton, VA*

Learning Objectives: Through lectures and panel discussions, workshop attendees will learn detailed information about the multiagency successful response to and processing of the January 2025 mid-air collision at the Ronald Reagan Washington National Airport. The involvement of a military helicopter and commercial airline as well as the incident location in the Potomac River triggered a multi-jurisdictional response involving local, state, federal and non-governmental agencies. Attendees will learn from incident responders the challenges faced, and strategic solutions implemented to recover, examine, identify, and return victims to their loved ones in a timely and dignified manner.

Impact Statement: The information provided during this workshop will impact the forensic science community by highlighting the challenges faced during a multi-jurisdictional response to a mass disaster. The content will include quickly devised response plans allowing operations to ramp up while maintaining daily workloads as well as innovative solutions taken to identify and reassociate victim remains.

Abstract Text: On January 29, 2025, an American Airlines commercial aircraft originating from Wichita, Kansas collided mid-air with a United States Army helicopter at the Ronald Reagan Washington National Airport during final approach. The collision caused both aircrafts to crash—the commercial plane descended into the Potomac River at an estimated depth of 5 to 15 feet, while the helicopter landed near the riverbank. The nature of the crash created a complex, multi-site recovery environment involving both water and shoreline. The incident resulted in 67 confirmed fatalities. The District of Columbia Office of the Chief Medical Examiner (DC OCME) assumed primary responsibility for fatality management following jurisdictional determination with Virginia authorities. This workshop will take the attendees through the multiple stages of a successful response to the highly complex mass disaster. The workshop is organized into three components of the disaster response: Facilitating External Operations; Maintaining Mortuary Operations; and The Role of DNA. Each component includes presentations by subject matter experts who were involved in the response. Also, there will be two discussion panels. The first component of the workshop, Facilitating External Operations, will begin with a presentation from the DC Chief Medical Examiner detailing a director's role in incident command, navigating pressures for administrators and the public, responding to family members and the media, and ensuring the staff's needs and concerns are met. A representative from the National Transportation Safety Board will follow and present on the specific steps taken to respond and assist local agencies as well as the unique challenges faced with an accident involving commercial and military aircraft. Finally, medicolegal death investigators will detail their role at the incident site and family assistance center. The second component, Maintaining Mortuary Operations, will include a presentation from a medical examiner detailing the agency's approach to ramp up capacity for the processing of incident victims while maintaining the daily caseload. The presentation will address establishing appropriate exam protocol for disaster victims, integrating external support from the Disaster Mortuary Operational Response Team (DMORT) and the Federal Bureau of Investigation (FBI) into operations, and efficient handling of fragmented remains. This component will also include the role of the anthropologist in coordinating decedent identification and fragment reassociation. The final component of the workshop, The Role of DNA, will detail the reliance on both rapid and traditional DNA analyses for victim identification and reassociation of the remains. Presentations will provide an overview of the DC Department of Forensic Sciences' (DFS) work with BODE, a DNA vendor laboratory, to quickly establish a contract for Rapid DNA analyses and to develop and communicate identification hypotheses. BODE staff will present on the laboratory's approach to increasing operations to meet the immediate demand. Meanwhile, DFS Forensic Biology Unit (FBU) staff will present their rapid response plan enabling the team to analyze the first batch of samples in 48 hours and a total of 94 samples throughout the response. Finally, FBU staff will describe the innovative reporting approach enabling OCME to easily reassociate the fragmented remains.

Mass Fatality; Search and Recovery; Victim Identification

W9 Investigating the Unsolved: Building Cold Case Programs Through Academic and Law Enforcement Partnerships

Jalika Waugh, PhD, Pinellas County Schools, Largo, FL; Sharon K. Moses, PhD*, Northern Arizona University, Flagstaff, AZ; Maylynn Burns*, Embry-Riddle Aeronautical University, Prescott, AZ; Kelly Crockett, MSF*S, Embry-Riddle Aeronautical University, Prescott, AZ; Edwin S. Cochran, MA*, Embry Riddle Aeronautical University, Prescott Valley, AZ*

Learning Objectives: By the end of this presentation, attendees will be able to design and implement a sustainable cold case program within a higher education institution. They will identify at least three open-source or intelligence-based investigative tools available in academic settings and demonstrate how to apply them in collaboration with law enforcement. Attendees will also be able to articulate the measurable benefits of student-law enforcement partnerships on both case outcomes and student competency development.

Impact Statement: This presentation will enhance the forensic science community's competence by equipping educators and students with practical frameworks to implement cold case programs in higher education, leveraging academic resources and investigative training. It will improve performance by fostering collaborative partnerships between colleges and law enforcement, enabling students to apply investigative techniques and open-source intelligence tools to real cases. Ultimately, these efforts can lead to meaningful stakeholder outcomes by supporting case resolution, delivering justice, and advancing public trust in forensic practices.

Abstract Text: This workshop session explores how institutions of higher education can play a pivotal role in assisting with unsolved cases through the development of academic cold case programs. Designed for educators, law enforcement professionals, and forensic practitioners, the session offers a step-by-step roadmap for creating and sustaining a cold case initiative that integrates academic resources, student involvement, and agency collaboration. This workshop session is grounded in the core fundamentals of forensic science and investigative work, including evidence-based reasoning, chain of custody, and crime scene integrity while emphasizing the importance of guiding students in the application of the scientific method and maintaining objectivity throughout the investigative process. Drawing on successful models across the country, participants will learn how to structure a program that not only enhances student competence in critical forensic and analytical skills, but also reinforces the importance of remaining neutral, impartial, and free from external influence while contributing meaningful investigative support to real-world cases. The session will highlight the mutual benefits of academic-law enforcement partnerships, including the development of student competence in critical thinking, evidence analysis, and intelligence gathering. Attendees will examine how to utilize open-source investigative tools, such as public records databases, social media analysis, and academic research platforms, to support cold case investigations. Case studies and interactive scenarios will illustrate the impact of applying these techniques to long-dormant investigations and how students, under faculty supervision, can contribute actionable insights. Additionally, the workshop will cover practical considerations such as program funding, managing case confidentiality, selecting appropriate cases, and aligning projects with academic learning outcomes. Attendees will leave with a resource toolkit, including sample syllabi, program planning guides, partnership templates, and investigative checklists to support immediate implementation at their institutions. Whether you are an educator seeking to enhance student engagement, a forensic professional interested in collaborative investigation, or a law enforcement representative looking for additional case support, this session will provide the knowledge and tools to transform unsolved cases into active educational opportunities with real-world impact.

Cold Case Investigations; Academic-Law Enforcement Partnerships; Open-Source Intelligence (OSINT)

W10 Behind the Evidence: The Impact of Vicarious Trauma in the Forensic Science Community

Kathryn Seigfried-Spellar, PhD, Michigan State University, East Lansing, MI; Carole E. Chaski, PhD*, Institute for Linguistic Evidence, Georgetown, DE; Sarah Avedschmidt, MD*, Sarah E. Avedschmidt, MD, Sacramento, CA; Pamela Marshall, PhD*, Duquesne University, Pittsburgh, PA; John P. Kenney, DDS, MS*, Davidson County TN Medical Examiner's Office, Nashville, TN; Peter Stout, PhD*, Houston Forensic Science Center, Houston, TX; Zain Bhaloo, MSc*, Canada Border Services Agency, Ottawa, Ontario, Canada; Joe C. Trevino III, DFS*, New York Police Department, Sunnyside, NY; Krystal R. Hans, PhD*, Purdue University, West Lafayette, IN; Lara Newell, MA*, Virginia Office of the Chief Medical Examiner, Richmond, VA; Joseph D. Remy, JD*, National White Collar Crime Center, Barrington, NJ; Katharine Pope, MA*, SNA International supporting the DPAA Mission, Fruitland, MD; Jessica L. Morel, DO*, Integrity Psychiatric Services PLLC, Fayetteville, NC; Justin Z. Goldstein, PhD*, NYC Office of Chief Medical Examiner, New York City, NY; Kenneth E. Melson, JD*, Formerly with the U.S. Department of Justice, Kinsale, VA; Mariah E. Moe, PhD*, Texas State University, San Marcos, TX; Liam Johnson, MA*, University of Nevada, Las Vegas, Las Vegas, NV*

Learning Objectives: This workshop is designed to help the forensic sciences community understand the serious implications of work-related stress. In the forensic sciences, work-related stress can lead to emotional burnout, physical illness (high blood pressure), and psychological effects like Post-Traumatic Stress Disorder (PTSD), depression, anxiety, and hypervigilance. These emotional and physical reactions may surface after one difficult case or after decades on the job. This workshop will include recommendations based on the academic literature, anecdotal stories, and open discussion on how to recognize the impact of trauma, build resiliency, and reduce mental health stigmas and barriers to help-seeking within the forensic science community.

Impact Statement: This workshop will impact the forensic sciences community by addressing mental health and well-being by discussing work-related stress, vicarious trauma, healthy and unhealthy coping mechanisms, and ways in which we can build resiliency and reduce mental health stigmas within our community.

Abstract Text: Research consistently shows that criminal justice professionals experience high rates of work-related stress as a part of the investigative process. Despite forensic scientists' prominent role in this process, literature on work-related stress has focused primarily on law enforcement officers investigating homicides, crimes against children, and other violent crimes. This workshop is designed to help the forensic sciences community understand the serious implications of work-related stress. In the forensic sciences, work-related stress can lead to emotional burnout, physical illness (high blood pressure), and psychological effects like PTSD, depression, anxiety, and hypervigilance. These emotional and physical reactions may surface after one difficult case, after decades on the job, or a life event such as having a child or the loss of a loved one. Our community also needs to understand how this trauma might be impacting those around us—our family and friends—or in academic units, the impact on students who are engaged in emotionally intensive coursework, research, clinical hours, or fieldwork/internships. This workshop will include recommendations based on the academic literature, anecdotal stories, and open discussion on how to recognize the impact of trauma, build resiliency, and reduce mental health stigmas and barriers to help-seeking within the forensic science community. The highlight of this workshop is our inclusive panel of speakers, who represent the various viewpoints and experiences of the different sections of the American Academy of Forensic Sciences.

Post Traumatic Stress Disorder; Stress; Resilience

W11 From Past to Present: Forensic Entomology Methods That Have Stood the Test of Time

Lavinia Iancu, PhD, University of North Dakota, Grand Forks, ND; Jeffrey D. Wells, PhD*, Florida International University, Miami, FL; Amanda Roe, PhD*, College of Saint Mary, Omaha, NE; Leon G. Higley, PhD*, University of Nebraska-Lincoln, Lincoln, NE; Neal H. Haskell, PhD*, Forensic Entomology Investigations, Rensselaer, IN; Christine M. Bogan, JD*, Rensselaer, IN; Olivia Minello, BS*, Las Vegas Metropolitan Police Department, CSI, Las Vegas, NV*

Learning Objectives: Attendees will gain a comprehensive understanding of the application of forensic entomology in medicolegal death investigations. They will learn to differentiate between Postmortem Interval (PMI), minimum Postmortem Interval (PMImin), and maximum Postmortem Interval (PMImax), understand insect succession and development, and apply this knowledge to real-world casework. Hands-on demonstrations will reinforce proper collection and preservation techniques.

Impact Statement: This workshop will enhance the competence of forensic professionals by deepening their understanding of entomological evidence and its interpretation. It will improve performance in the field and laboratory by reinforcing best practices in evidence collection and analysis. Ultimately, it will contribute to more accurate PMI estimations and stronger courtroom testimony, benefiting stakeholders in the justice system.

Abstract Text: This is a full-day workshop that highlights the enduring power of forensic entomology in death investigations, particularly in estimating the PMI. This full-day session will explore the scientific principles, practical applications, and legal considerations of forensic entomology, with a focus on methods that have remained reliable and relevant for decades. Through a combination of interactive lectures, case studies, and hands-on demonstrations, participants will learn how insect evidence is collected, analyzed, and presented in court. Topics include insect development and temperature effects, succession patterns, and the crime scene investigation perspective regarding entomological evidence. The workshop also includes a legal perspective on how entomological findings are presented and challenged in court, emphasizing the importance of precise terminology and scientifically defensible conclusions. Case presentations, bridging theory and practice, will offer participants real-world context for applying forensic entomology methods and understanding their impact on investigative and legal outcomes. A hands-on session will provide practical experience in evidence collection and preservation, while a panel discussion will offer a platform for collaborative dialog on current challenges and future directions in the field. This session is ideal for forensic scientists, death investigators, attorneys, and students who wish to deepen their understanding of forensic entomology and uphold the value of standardized, time-tested practices in forensic science.

W12 Back to the Basics: Criminal Investigation Assessment—Understanding the Behavior Behind the Crime

Patrick J. Zirpoli, Sherry Black Foundation, Milanville, PA; Erin Ryan, BA*, Sherry Black Foundation, Sandy, UT; Klaus C. Neudecker, MD*, Praxis für Begutachtungen, Landshut, Bayern, Germany; Kelsie Bryand, MS*, Sam Houston State University, Huntsville, TX; Katherine Brown, PhD*, Tarleton State University, RELLIS Academic Alliance, College Station, TX*

Learning Objectives: Upon completion of the course, the attendee will be able to: (1) cite the difference between Crime Assessment, an evidence-based process, versus Criminal Profiling, a psychological based process; (2) utilize the learned skill set to properly collect the information to decide the level of victim risk and offender risk; (3) compare the dynamics of a crime scene, homicidal pattern, and offender behavior characteristics, and select the proper sub-type and crime motivation; (4) assess the paralogical reasoning system and identify the level of victim and offender emotion; (5) recognize the difference between a crime driven by fantasy and one that contains no fantasy issues; (6) judge a criminal act and conclude whether the crime scene and offender are organized, disorganized, or both; (7) understand the behavior patterns of a Sexual Sadist, and how to identify and interact with them; and (8) understand the behavior pattern of Armin Meiwes, the Rotenburg Cannibal.

Impact Statement: Behavioral assessment has had a profound impact on the field of forensic science, serving as a bridge between psychological analysis and physical evidence. By systematically analyzing behavioral patterns, motives, and methods of offenders, Behavioral Assessment aids investigators in narrowing down suspect pools and understanding criminal minds. This integration of psychological insight enhances the interpretation of forensic evidence and often directs the focus of investigations, making forensic methodologies more targeted and effective. As a result, behavioral assessment not only contributes to more efficient crime-solving but also advances forensic science by promoting interdisciplinary collaboration and refining investigative strategies.

Abstract Text: Behavioral assessment is a method of investigation that utilizes key structures within the criminological continuum to examine the presence and/or absence of evidence found at the crime scene. Within this framework, there are major classifications, referred to as sub-types, which will be introduced and explained. These sub-types span across the criminal spectrum and manifest in the expression of pathological behaviors that can be recognized. Predicated upon these primary factors and coupled with additional principles, understanding the crime scene and offender actions through the crime continuum provides a critical understanding for the motives, methods, and opportunities of the crime.

The attendees will have the understanding that, although human experience is variable, crime patterns can be coded to reveal interlocking and separate vectors. Recurrent elements and themes are developed to group common factors for various desires, intentions, and plans. Therefore, dependent upon the intended outcome, the crimes can reveal differentiated power and anger issues, levels of intimacy, and idiosyncrasies. While acting out crime, the offender inadvertently leaves these clues available for investigation.

Attendees receive demonstrations through case presentations of how investigative techniques, evidence analysis, and behavior assessment help to characterize the offender based on the presence (and absence) of physical evidence. This process will be interactive where the attendees will offer their opinions and observations on the crime scenes and develop behavioral characteristics of the offender and crime.

Behavioral Science; Crime Scene Investigation; Sexual Crimes

W13 From General Knowledge to Case-Specific Insights: Navigating the Complexities of Trace and DNA Transfer, Persistence, Prevalence, and Recovery (TPPR) in Forensic Science Opinions

John M. Butler, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Jarrah R. Kennedy, MS*, Kansas City Police Crime Laboratory, Kansas City, MO; Niki Osborne, PhD*, Institute for Public Health and Forensic Science (PHF Science), Auckland, New Zealand; Melissa Taylor, BA*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: The goals of this presentation are to: (1) summarize key findings and recommendations from the National Institute of Standards and Technology (NIST) DNA Foundation Review and Human Factors reports as they relate to TPPR in forensic science; (2) identify common sources of uncertainty, controversy, and interpretive complexity when forming opinions on trace and DNA TPPR in specific case contexts; (3) critically evaluate when it is appropriate to offer expert opinion on TPPR and describe what type of data and reasoning should underpin such opinions; and (4) contribute to a structured taxonomy to categorize TPPR-related literature and scenarios during a collaborative classification exercise, contributing to the refinement of a searchable TPPR database.

Impact Statement: This workshop will advance the forensic science community's ability to engage with one of the field's most complex interpretive challenges: understanding and explaining trace and DNA TPPR in the context of a specific case. By promoting critical reflection on the scientific and cognitive underpinnings of TPPR opinions, introducing a taxonomy for structuring the TPPR literature, and piloting AI-supported approaches to literature synthesis, the workshop will contribute to more transparent, consistent, and scientifically grounded expert testimony.

Abstract Text: One of the most pressing challenges in forensic science is not just understanding trace and DNA TPPR, but determining *whether*—and *how*—to apply this understanding in the context of a specific case. This half-day workshop tackles the complex question facing forensic scientists: when (if ever) is it appropriate to offer expert opinion on TPPR, and what information should underpin such opinions? Participants will receive key insights from the NIST DNA Foundation Review and Human Factors report, exploring the scientific, cognitive, legal, and interpretive challenges associated with TPPR. Presenters will share an overview of current knowledge gaps, emerging controversies, and NIST-led efforts to develop a structured taxonomy to support a searchable TPPR database. The session will be interactive, blending presentations with opportunities for participant engagement and collaborative activities. Attendees will contribute to the development of tools and approaches aimed at organizing and applying scientific knowledge related to TPPR. The workshop will also explore how AI technologies can support more efficient and informed use of the TPPR literature in forensic practice. This workshop is intended for forensic practitioners, researchers, and legal professionals who grapple with the interpretive complexity of TPPR and seek to contribute to a more rigorous and defensible foundation for explaining what forensic results do, and do not, mean in the context of a case.

W14 Elementary, My Dear Chemist: Cracking the Mysteries of Unknown Substances

Agnes D. Winokur, PhD, Department of Justice, Drug Enforcement Administration, Dulles, VA; Alex J. Krotulski, PhD*, Center for Forensic Science Research & Education, Horsham, PA; Holly E. Pierzynski, MASc*, Cayman Chemical, Ann Arbor, MI; David B. Guthrie, PhD*, U.S. Drug Enforcement Administration, Dulles, VA*

Learning Objectives: During this workshop, attendees will learn the fundamental principles of complex chemical analysis and structure elucidation, to include systematic approaches to analytical testing and spectral interpretation, using Mass Spectrometry (MS), Infrared (IR) spectroscopy, and Nuclear Magnetic Resonance (NMR) spectroscopy. Attendees will learn how to evaluate fragmentation patterns, identify functional groups, and understand carbon and hydrogen connectivity patterns. In addition, the attendees will learn innovative techniques used by forensic laboratories to assist in identifying unknown substances encountered in illicit drug samples.

Impact Statement: This presentation will impact the forensic science community by demonstrating the utility and importance of comprehensive chemical testing to aid investigations across forensic science disciplines. This workshop will specifically focus on the identification and interpretation of emerging drug threats and Novel Psychoactive Substances (NPS). Additionally, the presentations will increase understanding of MS, IR, and NMR analysis and data interpretation.

Abstract Text: This workshop is being co-sponsored by the AAFS Opioids and Emerging Drugs ad hoc Committee and the Society of Forensic Toxicologists (SOFT) NPS Committee. NPS continue to grow in prevalence and popularity in the United States and on the global illicit drug market. As of March 2025, the United Nations Office on Drugs and Crime (UNODC) Early Warning Advisory (EWA) reported 1,302 individual NPS identified by forensic laboratories around the world. Synthetic opioids remain one of the fastest growing groups with the emergence of new substances on a monthly basis. Analytical profiles on these substances are very limited and often lacking as emerging substances are first encountered as unknown species by forensic laboratories. This workshop will focus on developing recognition strategies for when an unknown substance is identified and needs to be pursued further. Attendees will be provided with tools to establish and validate structure elucidation processes. The emergence of an unknown substance in an illicit drug sample has become more of a routine occurrence than an anomaly in forensic laboratories today as the drug supply has diversified. More often than not, these substances must be pursued and identified. Yet the structural elucidation process remains one of the most challenging aspects of forensic chemistry, requiring the integration of multiple analytical techniques and computational methods.

Illicit drugs are often chemically manipulated to create new substances of similar toxicity in order to bypass law enforcement controls. As existing precursors and chemicals are regulated, drug traffickers move to new chemicals and/or modified synthesis routes, resulting in new substances present in illicit drug samples. The identification is further complicated when no chemical profiles or reference materials exist. The workshop will begin with an overview of the fundamental processes of structural elucidation and the more traditional approaches of low- and high-resolution MS, 1D and 2D NMR spectroscopy, and IR spectroscopy. Participants will learn how to evaluate an unknown substance to determine if the unknown is of interest to pursue, as well as other innovative approaches to aid identification, such as the use of IRMS, ICPMS, and chemical synthesis. Several authentic case studies will be introduced to the attendees to help illustrate the role and impact that each technique plays in determining the unknown substance(s). The presenters will introduce how the collaboration between forensic toxicologists and seized drug chemists help in the identification of unknown substances. The participants will have a unique opportunity to evaluate and learn from the synthesis journey taken to identify various NPS, adulterants, and novel agents such as BTMPS and tetramethylfentanyl-related substances; the newest set of emerging substances for which reference materials are being commercially manufactured. The workshop will conclude with a discussion on how Artificial Intelligence (AI) and Machine Learning (ML) tools are being integrated into structural elucidation processes to enhance structural results and decrease response times.

W15 Building Scientific Confidence Through Validation of Forensic Methods

Melissa Taylor, BA, National Institute of Standards and Technology, Gaithersburg, MD*; Nicole S. Jones, MS*, RTI International, Oakton, VA; Henry Swofford, PhD*, National Institute of Standards and Technology, Gaithersburg, MD; Steven Lund, PhD*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: By the end of the workshop, participants will be able to: (1) define method validation and explain its importance in forensic science; (2) identify key components of a validation study and how to design them appropriately; (3) apply principles of validation to both subjective (human interpretation) and objective (instrumental) forensic methods; (4) access and utilize National Institute of Standards and Technology (NIST) -provided resources and reference materials for validation efforts; and (5) use the NIST Validation Assessment Tool (VAST) to support data analysis and reporting.

Impact Statement: This workshop equips forensic practitioners with the scientific foundation, practical tools, and regulatory insight required to design and execute validation studies that withstand courtroom scrutiny and satisfy modern accreditation demands. The workshop delivers measurable improvements in laboratory competence, courtroom credibility, and overall quality assurance, positioning participants to champion evidence-based practices across the forensic science community.

Abstract Text: Results of forensic analyses are critical to the work of law enforcement officers, attorneys, and courts, often influencing decisions that profoundly affect individual lives and public safety. A foundational component of trustworthy forensic science is the validation of the methods and tools used to produce these results. Method validation ensures that forensic techniques are reliable, reproducible, and fit for their intended purpose prior to implementation in casework. This four-hour workshop provides forensic practitioners with essential knowledge and practical skills to support laboratory validation efforts. Participants will gain a strong understanding of the principles of forensic method validation, including the design and execution of validation studies for both human interpretation and instrument-driven methods. Real-world exercises will be used to reinforce concepts and encourage interactive learning. In response to the forensic science community's call for greater guidance in this area, the NIST has developed a comprehensive suite of resources to assist laboratories with validation planning and execution. Workshop participants will receive detailed information on these resources, including access to reference data and materials, guidance documents, and tools to aid in the analysis and communication of validation results. A key component of the workshop is a hands-on demonstration of the NIST VAST. This interactive tool enables laboratories to conduct more robust and structured assessments of their validation data, enhancing transparency and scientific rigor.

Accuracy; Validation; Admissibility

W16 The American Board of Forensic Anthropology Presents: How Forensic Anthropology Contributes to Trauma Analyses—A Primer for Medical Examiners/Coroners and the Medicolegal Community

Angela Soler, PhD, NYC Office of the Chief Medical Examiner, New York, NY; Erin B. Waxenbaum, PhD*, Northwestern University, Evanston, IL; Kristen Hartnett-McCann, PhD*, Connecticut Office of the Chief Medical Examiner, Farmington, CT; Bradley Adams, PhD*, Lawrence, KS; Christopher W. Rainwater, PhD*, Tarrant County Medical Examiner, Fort Worth, TX; Melissa A. Pasquale-Styles, MD*, Connecticut Office of the Chief Medical Examiner, Farmington, CT; Heather M. Garvin, PhD*, Des Moines University, West Des Moines, IA*

Learning Objectives: After attending this workshop, attendees will: (1) understand how forensic anthropologists contribute to the analysis of cartilaginous and skeletal trauma in cases of suspected neck compression, pediatric trauma, and dismemberment; (2) recognize the forensic anthropologist's expertise in cartilaginous and skeletal trauma, even in cases where the decedent is not skeletonized; and (3) understand the importance of using a qualified, vetted, board-certified forensic anthropologist with experience in the examination and interpretation of skeletal and cartilaginous trauma.

Impact Statement: This workshop is relevant to medical examiners, coroners, medicolegal death investigators, law enforcement, and legal professionals interested in learning about how forensic anthropological analyses of skeletal and cartilaginous trauma contribute to the death investigation. The field of forensic anthropology has grown in recent years, with more practitioners embedded within medical examiner and coroner offices. As forensic anthropologists have become more integral to the death investigation, they have expanded outside of the more traditional analysis of skeletonized remains and have developed expertise in skeletal and cartilaginous trauma interpretation that contributes to cases of fresh, decomposed, burned, and skeletonized remains.

Abstract Text: This workshop was developed by the American Board of Forensic Anthropology (ABFA) Outreach Committee to highlight the important contributions of certified forensic anthropologists in the examination of skeletal and cartilaginous trauma in medicolegal death investigations. This workshop will specifically address the forensic anthropologist's expertise in cases of suspected neck compression, pediatric trauma, and dismemberment. The forensic anthropologist provides information that may contribute to the final determination of cause and manner of death, identify and document prior (healed) skeletal or cartilaginous trauma that may be relevant to the investigation, and help identify what tools or weapons may have caused skeletal or cartilaginous injury. In addition, the forensic anthropologist can serve as an expert witness in court and provide visual aids, such as diagrams, photographs, casts, and 3D printed exemplars that are more easily visualized and understood by a jury. The workshop will also review the imperative need of a Board-Certified Forensic Anthropologist in these types of trauma investigations. ABFA Certified Forensic Anthropology Diplomates (D-ABFAs) have passed a rigorous application, evaluation, and examination process that demonstrates competency in the discipline. They are required to complete continuing education, undergo a recertification process, and sign an annual ethics statement. Using a board-certified D-ABFA provides quality assurance and ensures that the anthropologist has the requisite training in legal matters and sufficient experience.

Trauma; Medicolegal Death Investigation; Forensic Anthropology

W17 That Was Then, This Is Now—Bridging the Gap Between Genetic Genealogy and the Forensic Communities

Colleen M. Fitzpatrick, PhD, Identifinders International LLC, Fountain Valley, CA; Ray A. Wickenheiser, DPS*, SupreMEtric, Youngsville, LA; Claire L. Glynn, PhD*, University of New Haven and Henry C. Lee Institute of Forensic Science, West Haven, CT; Wendy Mclean, BS*, UNT Center for Human Identification, Fort Worth, TX*

Learning Objectives: Upon attending this presentation, attendees will learn how genetic genealogists, law enforcement personnel, and forensic scientists can develop careers in Forensic Investigative Genetic Genealogy (FIGG) through an understanding of the professional, ethical, legal, and accreditation-related standards they must meet to be compliant with the requirements of the judicial system.

Impact Statement: This workshop will impact the forensic and genealogical communities by demonstrating the need for a responsible and ethical development of an accreditation for independent FIGG practitioners that can bridge the gap with forensic policies, procedures, and standards, along with the legal system they comprise.

Abstract Text: The challenge in developing a healthy relationship between the forensic and genetic genealogical communities is that forensics policies, procedures, and standards, along with the legal system they comprise, have been developed over centuries, while the genetic genealogy community is only 25 years old and has developed as mostly unstructured and unregulated. Developing compliant policies, procedures, and standards that enable genetic genealogists to move into the FIGG space is critical to supporting this new field as it gains universal acceptance. Training and certificate programs have been created for members of law enforcement and independent FIGG practitioners, most of which cover the basics of IGG research, but practitioners still need to acquire practical experience and to establish a proven track record to find employment in the very competitive IGG job market. Even so, while the number of employment opportunities is extremely limited in the IGG space, the number of cases waiting to be solved is enormous. The remedy for this imbalance could lie in building genetic genealogy standards compliant with forensic requirements to allow independent FIGG practitioners to establish credibility within the legal system. Doing so would undoubtedly increase the number of job opportunities and the access of independent FIGG practitioners to a larger number of cases.

This workshop will discuss how to bridge the gap between the professional demands of the forensic community with the unstructured nature of the genetic genealogy community. Topics to be covered are: (1) the development of Forensic Investigative Genetic Genealogy (FIGG) as a career; (2) the National Technology Validation Implementation Collaborative (NTVIC) recommendations for the IGG community; (3) working within an International Organization for Standardization (ISO) 17025-accredited laboratory; (4) how to increase the number of job opportunities in FIGG; and (5) a closing panel discussion.

FGG; Accreditation; Genealogy

W18 Teaching with Care: Understanding Trauma-Informed Pedagogy and Its Application in Forensic Science Education

Krystal R. Hans, PhD, Purdue University, West Lafayette, IN; Kimberlee S. Moran, MSc*, Rutgers University- Camden, Camden, NJ; Katie Wiggins, EdD*, Uprooted: Where Healing is Planted, Jacksonville, FL; Ryan Backmann*, Project Cold Case, Jacksonville, FL; Charlie Shunick, MS*, Delgado Community College/Resource Association for Missing People, New Orleans, LA; Leisa J. Nichols-Drew, MSc*, De Montfort University, Leicester, England, United Kingdom*

Learning Objectives: This workshop will provide attendees with a robust understanding of how Post-Traumatic Stress Disorder (PTSD) and vicarious trauma impact forensic science students during their education and career preparation, using real-life examples to highlight the limitations of traditional teaching approaches. Attendees will be introduced to Trauma-Informed Pedagogy (TIP) and learn practical strategies for applying TIP in classroom and laboratory settings to better support student well-being. Finally, attendees will examine how mental health and wellness are integrated into forensic science higher education in the United Kingdom. Attendees will leave with tools to create safer, more inclusive learning environments that foster resilience and emotional health.

Impact Statement: This workshop will enhance educators' competence by deepening their understanding of trauma and equipping them with trauma-informed teaching strategies tailored to forensic science students. By applying these strategies, educators can improve their performance in creating emotionally safe, supportive, and effective learning environments. Ultimately, this shift in educational practice will lead to better outcomes for students, including increased resilience in the workplace, reduced burnout, and a stronger, more ethically grounded forensic science workforce.

Abstract Text: TIP is an educational approach that acknowledges the impact of trauma on learners and encourages educators to consider the emotional and psychological well-being of students alongside academic performance.[1] This workshop will explore the particular relevance of TIP in forensic science education, where students are regularly exposed to potentially distressing content such as crime scene imagery, autopsy reports, and case studies involving sexual violence or death.[2,3] Some students may enter forensic science programs with existing trauma histories or may develop secondary traumatic stress or vicarious trauma through repeated exposure to sensitive material. TIP offers a structured way to mitigate these risks and promote resilience. Educators trained in TIP are better prepared to recognize signs of trauma, respond sensitively, and create learning environments that prioritize safety, empathy, and respect. The workshop will explore how TIP can be applied in forensic science through curriculum design and teaching strategies that reduce retraumatization and support student well-being. This includes the use of content warnings, flexible assessments, reflective practices, and clear communication. Real-world examples and case studies will highlight how trauma-informed approaches have improved outcomes for students. Participants will also reflect on their own teaching and identify ways to move toward a more trauma-responsive model. Beyond supporting students during their academic journey, TIP also prepares them for careers that may involve exposure to vicarious trauma.[4] This workshop will examine how forensic programs can promote psychological preparedness by helping students recognize signs of distress, develop coping strategies, and seek support when needed. By integrating TIP early in education, students can build resilience, self-awareness, and emotional intelligence as core professional competencies. This proactive approach supports a broader culture shift in forensic education—one that balances technical training with emotional sustainability. As mental health concerns grow among university students, TIP offers a timely, evidence-based response.[5] Embedding trauma-informed practices can improve student engagement, retention, and create a more inclusive, supportive learning community. Ultimately, TIP helps cultivate forensic science professionals who are emotionally resilient, ethically aware, and professionally competent. These graduates are not only prepared to handle the psychological demands of their roles but are also more likely to contribute to healthier workplaces and to better support the communities they serve.

W19 Cognitive Bias and Error in the Forensic Sciences

Paul S. Uribe, MD, Fort Bend County Medical Examiner Office, Richmond, TX; Tiffany A. Roy, JD, MSFS*, ForensicAid, LLC, Singer Island, FL; Allison Lewis, JD*, The Legal Aid Society, New York, NY; Marion Davidson, MSc*;University College London, Baltimore, MD; Jennifer G. Solari, JD*, Baker & Hostetler, LLP, Savannah, GA; George F. Jackson, PhD*, Office of the Chief State Medical Examiner, Trenton, NJ; William Oliver, MD*, East Carolina University, Seymour, TN; Michelle Rippy, EdD*, California State University East Bay, Hayward, CA*

Learning Objectives: This workshop aims to equip forensic professionals with knowledge of cognitive biases impacting forensic science. Participants will learn to identify the effects of cognitive bias and how they relate to errors in decision-making across multiple forensic disciplines. The program fosters interdisciplinary collaboration to enhance accuracy in medicolegal investigations and death certification.

Impact Statement: By addressing cognitive bias, this workshop will improve the reliability of forensic analyses and strengthen justice system outcomes. It empowers professionals to implement bias-mitigation strategies, fostering greater trust in forensic evidence.

Abstract Text: This workshop offers a comprehensive exploration of cognitive biases affecting forensic science and medicolegal investigations. It brings together diverse perspectives from forensic pathologists, medicolegal death investigators, toxicologists, DNA analysts, fingerprint analysts, prosecutors, defense attorneys, and cognitive scientists. Through interactive presentations and case-based discussions, participants will examine how biases—such as confirmation bias, anchoring, and contextual bias—can influence forensic decision-making and lead to errors in analysis, interpretation, and courtroom testimony. The workshop will cover practical strategies for recognizing and mitigating biases in various forensic disciplines, drawing on real-world examples and interdisciplinary insights. Forensic pathologists and medicolegal death investigators will share approaches to maintaining objectivity in autopsy and scene investigations. Toxicologists and DNA analysts will discuss methods to standardize interpretations and reduce subjective errors. Fingerprint analysts will explore challenges in pattern recognition and verification processes. Legal professionals, including prosecutors and defense attorneys, will provide perspectives on how biases in forensic evidence impact case outcomes and judicial fairness. Cognitive scientists will ground these discussions in the latest research on human cognition, offering evidence-based tools to enhance decision-making. Attendees will participate in hands-on exercises to apply bias-mitigation techniques, fostering skills that translate directly to their practice. By promoting interdisciplinary dialog, the workshop aims to build a collaborative framework for improving the reliability and credibility of forensic science. This program is ideal for forensic practitioners, legal professionals, and researchers seeking to advance the integrity of medicolegal investigations and ensure more unbiased outcomes

W20 The Case of the Contextual Conundrum: Can We Have Forensic Science Without Context?

Michelle D. Miranda, PhD, Center for Criminal Justice Studies, Farmingdale, NY; Patrick Buzzini, PhD*, Sam Houston State University, Huntsville, TX; Claude Roux, PhD*, University of Technology Sydney (UTS), Ultimo, New South Wales, Australia; Sheila Willis, DSc*, Leverhulme Research Centre for Forensic Science, Dublin, Ireland*

Learning Objectives: After attending this workshop, attendees will (1) Understand the foundational role played by context across all forensic science activities; (2) Learn that context can be present in different forms and typologies; (3) Understand how context is critical to every step of the forensic science process: investigations, scene investigation including trace detection and signification, event reconstruction, laboratory analysis, as well as evaluation and reporting.

Impact Statement: This presentation will impact the forensic science community by emphasizing foundational principles of forensic science, exploring the effect of context in different ways, and illustrating that meaningful interpretation can only be carried out inconsideration of context.

Abstract Text: This workshop highlights the critical role of context in forensic science practice, emphasizing that context is not just a concept related to relevance—it is foundational to the discipline. We begin by defining and discussing "context" within the forensic science framework and examining its various forms, including those shaped by case-specific circumstances and the perspectives of forensic scientists and other stakeholders.

A key focus will be on how meaningful interpretations depend on the information available during an investigation and the recognition that every participant brings their own contextual lens to the process. By understanding the foundational role of context in forensic science, including its polymorphisms, how it can be integrated into forensic science endeavors, and linking the topic "back to basics," forensic practitioners will be better equipped to deliver relevant and meaningful conclusions.

Participants will appreciate the nuances of context, particularly the importance of asking the right questions, the distinction between task-relevant and task-irrelevant information, and how in these influence forensic science processes. The workshop will then address how context impacts decision-making throughout every stage of forensic problem-solving, and how information can be utilized to confirm or refute an account of events. Finally, a review of various reporting schemes following comparative examinations that have been used in the forensic practice will be examined in the light of context, and their implications on the understanding of the intended recipient.

Forensic science reports are received by various actors in the process. There is quite a skill involved to ensure that each participant gets the information they need in a manner that suits them. The investigator may welcome any information that reduces the pool of suspects while a court will need assistance in evaluation. The information from today's forensic science laboratories also have the potential to identify crime patterns, help evidence-based and intelligence-led policing models, and increase public safety by assisting in crime reduction. Capitalizing on these capabilities requires consideration of context and the processes in place to record findings in various ways.

Context; Decision-Making; Scientific Methodology

W22 Ethics in Forensics: Turning Data Into Dialog

Kevin P. Kulbacki, MSFS, KDX Forensics, Chicago, IL; Anjali Ranadive, JD*, SciLawForensics, Ltd, Phoenix, AZ; Sarah Chu, PhD*, Perlmutter Center for Legal Justice at Cardozo Law, New York, NY; Lisa Montanez, MSFS*, The Perlmutter Center for Legal Justice, Cardozo School of Law, Yeshiva University, New York, NY; Max Houck, PhD*, FIU Global Forensic & Justice Center, Buffalo, NY; Kyla Wells, JD*, Federal Defenders of New York, Inc., New York, NY*

Learning Objectives: After attending this presentation, attendees will gain a deeper understanding of common sources of ethical strain within forensic science. They will be able to understand patterns that link headline failures with quieter, everyday pressures within the laboratory and how cultural factors may inhibit candid discussion of these issues. Finally, attendees will be better equipped to discuss potential reforms to rectify and minimize these issues, both within their own laboratories and throughout the broader forensic science community.

Impact Statement: This presentation will impact the forensic science community by creating candid dialogs about the state of ethics in forensic science. It will reveal patterns behind headline failures and the quieter, everyday pressures that are rarely documented, thereby widening our understanding of how ethical strain emerges and persists across disciplines. It will lay a shared foundation for future research, training, and policy discussions that treat ethics as a central scientific question rather than a peripheral compliance task.

Abstract Text: Ethical integrity is the bedrock of forensic science. It shapes how evidence is generated, interpreted, and presented in court, and it is essential to sustaining public trust. Yet the field still contends with organizational expectations, workload and turnaround pressures, and subtle cognitive biases that can compromise objectivity. Almost every practitioner can point to an "ethics story." a moment when tight deadlines, resource limitations, internal pressures, or external expectations may have impacted casework. These experiences are instructive but seldom shared, leaving lessons uncollected and reforms uneven. This full-day interactive workshop creates a structured forum to discuss the state of ethics in forensic science. It will analyze headline-making lapses and contextualize the underlying problems with new survey data on ethics from forensic scientists. Discussion will focus on patterns, not personalities, to surface systemic contributors and practical safeguards. The data will be paired with candid discussions of how external oversight of forensic laboratories works in practice. Participants will consider the ripple effects ethical failures can have on investigations, verdicts, and public confidence in the justice system. The workshop will culminate in a solutions-focused panel and action-planning session, equipping participants to foster candid dialog, strengthen accountability, and begin the conversation on a more ethically robust forensic science. Attendees will leave with concrete next steps they can implement in their own laboratories and units.

Ethics; Oversight; Transparency

W23 Forensic Investigation of Sudden Deaths in the Young: Who, When, and How

Simone Grassi, MD, PhD, University of Florence, Florence, Toscana, Italy; Cristina Mondello, PhD*, University of Messina, Messina, Sicilia, Italy; Antonio Oliva, MD, PhD*, Università Cattolica del Sacro Cuore, Rome, Lazio, Italy; Andrea Costantino, MD*, Careggi University Hospital, Florence, Toscana, Italy*

Learning Objectives: Attendees will be: (1) looking at sudden cardiac death of the young as both a forensic and public health issue; (2) learning the whole process of forensic investigation, from the family history of the victim to the interpretation of molecular autopsy, and (3) learning how to combine ambiguous toxicology, autopsy, histology, and molecular autopsy data in sudden deaths

Impact Statement: The workshop wants to transmit a basic but complete knowledge of what the forensic routine is when a young (younger than 35 years) person suddenly dies, especially when the autopsy results are ambiguous/inconclusive. Real cases will help the audience to simulate decision-making in critical contexts and understand the cost/benefit ratio in highly challenging cases. The workshop hopefully will help to transmit a combined forensic/public health perspective on sudden death, helping forensic experts to transform a tragic event into a chance for the survivors to prevent sudden death.

Abstract Text: We propose a half-day workshop with five segments, with interactive lectures and discussion of real cases. The topic is sudden death in the young, a relatively frequent occurrence that is mainly due to cardiac disorders, in particular to inherited cardiac conditions whose first manifestation is death. Since these conditions are inheritable in an autosomal dominant fashion, making a postmortem diagnosis is the only method to allow timely preventive interventions for the first-degree family. In young victims, autopsy findings are generally ambiguous/subtle and combining them with postmortem molecular information is often the only way to make a reliable diagnosis. Moreover, a specific microscopic analysis of the recurring patterns in early cardiomyopathies and in specific channelopathies (like Brugada Syndrome) is extremely helpful in the decision-making and thus is essential for the forensic pathologist.

1. Introduction to sudden death: a medicolegal perspective. This introduction will provide a definition of sudden death and sudden cardiac death; their prevalence and legal and social impact will be discussed.
2. The autopsy investigation in sudden cardiac death: introducing the burden of sudden unexplained death related to cardiovascular diseases and framing its definitions and epidemiology, as well as the postmortem investigations. In this section, the role of autopsy as the first and last opportunity to make an accurate diagnosis in sudden cardiac death will be argued, focusing on autopsy procedures looking for cardiac causes of sudden death. Also, the importance of both what clinical and circumstantial data from the deceased and his family should be collected and which additional postmortem investigations may be performed (i.e., imaging, toxicology, biochemistry) will be discussed.
3. Best practice for heart microscopic examination and interpretation of microscopic data: best forensic practice for heart microscopic examination, starting from the sampling to the choice of the correct staining/technique. This section will emphasize that careful microscopic analysis is crucial in the investigation of sudden deaths. Since the variable expressivity of the inherited arrhythmogenic disorders, particular focus will be put on when a specific feature (like myocardial fibrosis or disarray) can be considered “normal” and when it should be seen as a red flag to indicate further analysis.
4. The indication of molecular testing and the integration of its results with other forensic evidence. It will be explained that sudden cardiac death in the young is mainly caused by disorders that are inherited in an autosomal dominant way and have incomplete penetrance/variable expressivity. “What can we expect from postmortem genetic testing?” will be the core question, with an expression of when it should be indicated, how it is performed, and what its yield is. Main limitations will be discussed, such as how to interpret variants of unknown significance. Finally, some real cases of subtle autopsy/histology findings in the presence of complex genetic anomalies will be discussed.
5. Q&A period.

Sudden Cardiac Death; Young Victims; Arrhythmogenic Disorders

W25 Testifying Without a Net: Navigating Activity-Level Evaluation Questions Without Formal Evaluation

Tim Kalafut, PhD, Sam Houston State University, Huntsville, TX; Simone Gittelson, PhD*, The George Washington University and DC Department of Forensic Sciences, Washington, DC; Ray A. Wickenheiser, DPS*, SupreMEtric, Youngsville, LA; Michael A. Marciano, PhD*, Syracuse University, Syracuse, NY; Michael Bissonnette, MS*, Centre of Forensic Sciences, Ontario, Canada*

Learning Objectives: After attending this workshop, attendees will have an alternate strategy to answer questions about transfer and persistence at trial. They will know how to correctly formulate activity-level propositions, apply the Case Assessment and Interpretation framework, support their opinions with data, and answer questions without transposing the conditional. Participants will be given options that can assist in developing a protocol and training program for use in their own casework.

Impact Statement: This presentation will impact the forensic science community by providing guidance on how to answer activity-level questions on biological results during testimony when no formal Activity-Level Evaluation (ALE) had been conducted. The strategies discussed will provide the participants with a way to deliver answers that are useful to the court and based on data, emphasizing balance, logic, and transparency.

Abstract Text: The United States faces unique challenges in the ALE of DNA results. Activity level inquiries about the expert's findings happen in real time while at trial, often with no warning for the expert. These questions are often about "transfer" and do not allow for a model-driven approach with formal reporting. Answers of the type, "Yes, it's possible …" are problematic because they offer no useful information. However, expert witnesses continue to be asked these questions, and offering a response that doesn't address the evidence in the case is not helpful either for the trier of fact. There are numerous guidelines for a formal, model-driven approach that must be done ahead of trial and can be reported and disclosed. However, if this is not possible, there are no current guidelines for how to handle ALE questions other than to discuss the limitations of the reported sub-source level evaluation. This workshop addresses the missing middle ground, focusing on testimony when no model-driven ALE was formally reported. A new working group of North American practitioners from federal, state, and local laboratories have developed a document of best practices for a judgement-based evaluation to meet the realities of testimony. Guidelines will be presented on strategies for training and implementation of a real-world approach designed to prioritize rigor, transparency, balance, logic, and traceability.

Activity Level; Transfer; Expert Testimony

W26 Advancing the Adoption of Artificial Intelligence in Forensic Science: Use Cases, Innovation Pathways, and a Procurement Framework

Niki Osborne, PhD, Institute for Public Health and Forensic Science (PHF Science), Auckland, New Zealand; Melissa Taylor, BA*, National Institute of Standards and Technology, Gaithersburg, MD; Henry Swofford, PhD*, National Institute of Standards and Technology, Gaithersburg, MD; Janet K. Stacey, MSc*, The New Zealand Institute of Public Health and Forensic Science (PHF Science), Auckland, New Zealand*

Learning Objectives: The goals of this workshop are to: (1) identify and describe high-impact AI use cases relevant to forensic science, including applications in case management, evidence analysis, research, training, and quality assurance; (2) access and contribute to a shared use case library and taxonomy, designed to accelerate innovation by aligning developer efforts with real-world forensic needs; (3) explain the core principles of the National Institute of Standards and Technology (NIST) AI Risk Management Framework (RMF) and the Responsible AI Framework for Forensic Science and how these tools support effective and transparent AI adoption; and (4) explore a forensic-specific procurement framework to evaluate the readiness, fit-for-purpose design, and scalability of AI tools under consideration for operational use.

Impact Statement: This workshop will equip forensic scientists, quality managers, researchers, and legal practitioners with the tools and frameworks needed to make informed decisions about adopting AI technologies in forensic science. By introducing structured use cases, shared terminology, and risk management and procurement frameworks, the session aims to bridge the gap between technical innovation and operational readiness. The outcomes will support the development of innovative, transparent, and fit-for-purpose AI-enabled applications in forensic science.

Abstract Text: Artificial Intelligence (AI) presents transformative opportunities for the field of forensic science, with the potential to accelerate workflows, improve efficiency, and provide new insights across a range of forensic disciplines. From streamlining case management and automating administrative tasks to enhancing evidence analysis, quality assurance, training, and research, AI has the capacity to support forensic science service providers in meeting growing demands while maintaining high standards of accuracy and accountability. This half-day workshop is designed to support the responsible and innovative adoption of AI-enabled tools in forensic settings. It will spotlight real-world use cases and explore emerging possibilities, with a focus on identifying and reducing barriers to implementation. Participants will engage with an evolving library of AI use cases, gaining hands-on experience in how to evaluate opportunities for integration in their own organizations. The workshop also aims to foster collaboration between developers and the forensic science community, bridging gaps in language, expectations, and priorities. NIST is actively leading efforts to advance AI adoption in forensic science through initiatives such as mapping AI tools relevant to forensic workflows, developing a shared forensic-AI taxonomy, and supporting the design of a forensic-specific AI procurement framework. Participants will also explore practical governance tools such as the NIST AI Risk Management Framework and the Responsible AI Framework for Forensic Science to support innovation while promoting transparency, reliability, and alignment with legal, scientific, and operational requirements.[1,2]

W27 Homicide-Suicide: Back to the Basics

Alan R. Felthous, MD, Saint Louis University School of Medicine, St. Louis, MO; Paulyann Maclayton, MD*, Harris County Institute of Forensic Sciences, Manvel, TX; Daniel A. Martell, PhD*, Forensic Neuroscience Consultants, APPC, Irvine, CA; Chanchal K. Kahlon, MD*, SSM Saint Louis University Hospital, Saint Louis, MO; Tabitha Ward, MD*, Bexar County Medical Examiner's Office, San Antonio, TX; Julian Samuel, MBBS*, Harris County of Institute of Forensic Sciences, Houston, TX; Felice F. Carabellese, MBBS*, University of Bari, Puglia, Italy; Emma Henrie, MD*, Harris County Institute of Forensic Sciences, Houston, TX; Lia Parente, PsyD*, University of Rome Sapienza, Trani, Puglia, Italy; Emily Rodgers, DO*, SSM Saint Louis University, Saint Louis, MO; Delavar Safari, MD*, SSM Saint Louis University Hospital, Saint Louis, MO*

Learning Objectives: After attending this workshop, attendees will: (1) understand basic procedures in medical examinations for determining that deaths were homicide-suicide and the type of Homicide-Suicide (HS); (2) gain an appreciation of the two-part classification of HS that addresses the psychopathology of the perpetrator and their relationship with the victim(s); (3) recognize the three domains of HS: psychopathology, stressors, and vector (cognitive components of motivation); and (4) recognize from example how physical findings of the deceased can relate to the perpetrator's mindset during the act.

Impact Statement: This workshop should impart a deeper understanding of the interrelationship between autopsy findings and psychological issues behind HS acts. Practitioners can recognize that the classification of all HS pertains to individual, unique cases, and careful examination of individual cases adds to the usefulness of the broader classification. Collaboration between pathologists and behavioral scientists may enhance understanding of these tragic events and provide preventive insights.

Abstract Text: In line with the conference theme "Back to Basics: The Fundamentals of Forensic Science," this workshop explores the interplay between psychological pathology and physical trauma in fatal domestic violence-related HS across Harris and Bexar Counties, TX, and mass HS cases nationally and internationally. These emotionally charged events underscore the critical role of the forensic pathologist in objectively applying scientific principles to complex scenes—reinforcing our allegiance to the evidence rather than to any narrative. HS, especially those rooted in intimate partner violence and familial relationships, provide a unique lens through which to understand the convergence of internal psychological breakdown and external lethal behavior. Our workshop integrates psychological typologies and forensic findings to paint a holistic picture of these tragedies. Case reviews will include:

- A familicide involving parents and their 7-year-old son, where the teenage daughter survived while in the home.
- A spousal HS committed in the presence of a child.
- A mother and son found deceased in an extended-stay hotel.
- A murder-suicide involving a husband, uncle, and cousin, sparing other family members.
- A delayed suicide following the murder of a spouse and two teens.
- Multiple familicides in settings of divorce or unknown triggers.

These cases will be examined not only for injury patterns, range of fire, and number of wounds, but also for clues into the perpetrator's mindset and motivations. Victim selection—why certain family members are spared—will be explored through both pathological and psychological frameworks. We incorporate the latest HS classification models, including the tripartite framework by Felthous et al., which analyzes: (1) the actor's psychopathology and ego structure, (2) chronic or acute stressors, and (3) the motivational vector driving the act.[1] Psychological categories include depression, psychosis, alcohol misuse, sociopathy, and impulsive aggression. These internal states, paired with relationship context—intimate, parental, or adversarial—shape the trajectory of the homicide-suicide event. Dr. Paulyann Maclayton will present trends in domestic violence-related HS in Harris County, focusing on how acts of violence often occur during periods of victim separation or attempts to flee. Drs. Emma Henrie, Tabitha Ward, and Julian Samuel will analyze specific cases involving parents, children, and extended relatives, offering hypotheses on spared victims and behavioral warning signs. International perspectives will be provided by Drs. Parente and Carabellese, who will examine Italian femicides followed by suicides, alongside recent legislative responses. Dr. Chanchal Kahlon will examine parricide-suicide. Dr. Chanchal Kahlon will examine parricide-suicide. Dr. Dan Martell will explore mass HS events, and Dr. Delavar Safari will share findings on school shooters. Dr. Rodgers will discuss cult-related HS, highlighting psychological manipulation and leader-follower dynamics. By connecting the psychology of the perpetrator with the pathology of the act, this workshop offers a multidisciplinary approach that deepens understanding, improves investigative accuracy, and underscores the importance of practitioner well-being in the face of repeated trauma exposure. The forensic scientist must serve as both a scientist and a witness to some of society's most devastating ruptures—bringing clarity to chaos through science and compassion.

W28 Forensic Postmortem Imaging and Medicolegal Death Investigations

Summer J. Decker, PhD, University of Southern California Keck School of Medicine, Los Angeles, CA; Fabrice Dedouit, MD, PhD*, Toulouse Hospital, Toulouse, Midi-Pyrenees, France; Jamie M. Elifritz, MD*, Forensic Radiology Group, Destin, FL; Barbara Fliss, MD*, University Medical Center of the Johannes Gutenberg-University Mainz, Institute of Forensic Medicine, Mainz, Rheinland-Pfalz, Germany; Jonathan M. Ford, PhD*, University of Southern California, Los Angeles, CA; Lars Ebert, PhD*, Zurich Forensic Science Institute, Zurich, Switzerland; Michael Thali, MD*, University Zurich, Zurich, Switzerland; Edward Mazuchowski, MD, PhD*, Armed Forces Medical Examiner System, Dover AFB, DE; Heather S. Jarrell, MD*, Office of the Medical Investigator, University of New Mexico School of Medicine, Alburquerque, NM; Yanko G. Kolev, MD, PhD*, Department of General Medicine, Forensic Medicine and Deontology, Medical University, Pleven, Bulgaria*

Learning Objectives: The goals of this workshop are to: (1) describe the foundational principles of Postmortem Computed Tomography (PMCT) and its growing role in medicolegal death investigations, with attention to its global adoption and implementation; (2) recognize key PMCT findings across a range of cases—including natural disease, trauma, drug-related deaths, and unidentified remains—with attention to interpretive pearls and common pitfalls; (3) identify practical considerations for implementing a PMCT service, including equipment selection, workflow design, and interdisciplinary collaboration between radiologists and death investigators; (4) engage in hands-on presentations, gaining experience with Picture Archiving and Communication Systems (PACS), review real PMCT cases using a web-based PACS platform, guided by expert tips, interpretation strategies, and feedback; and (5) evaluate emerging technologies and legal applications of PMCT, such as 3D reconstructions and postmortem angiography, and understand their value in documentation, expert consultation, and courtroom presentation.

Impact Statement: This workshop advances the integration of PMCT into medicolegal death investigation by offering practical guidance, case-based learning, and global expertise. Participants will gain essential skills for implementing and interpreting PMCT, explore its application in diverse death scenarios, and understand its value in legal proceedings. By fostering international collaboration and highlighting emerging technologies, this program supports the standardization and broader adoption of PMCT in forensic practice.

Abstract Text: This workshop is designed to focus on PMCT and advanced imaging, drawing on the expertise of a global consortium of leaders in the field. Participants will explore a comprehensive array of topics ranging from foundational principles to advanced applications. Sessions will include guidance on establishing a PMCT service, engaging case reviews with interpretation pearls from diverse international perspectives, and focused discussions on the role of PMCT in drug-related deaths and the identification of unknown remains. The workshop also highlights the importance of collaboration between radiologists and medicolegal death investigators and introduces emerging technologies and innovative applications shaping the future of forensic imaging. This workshop will provide an overview of how the different radiologic imaging modalities have been incorporated into specific medicolegal death investigations. Through directed lectures and case presentations, the advantages and limitations of the modalities will be presented. How postmortem radiology enhances the medicolegal death investigation will be discussed. Topics include a spectrum of natural and unnatural deaths, postmortem changes and artifacts, basics of PACS functionalities and interpretation, and pearls and pitfalls. The incorporation of these findings into legal proceedings will also be discussed. A panel discussion allows participants to engage with presenters and discuss how to implement forensic imaging into their medicolegal practice. Given the breadth of this topic, our goal is to offer something for everyone—whether you're new to forensic imaging, looking to deepen your interpretive skills, or interested in the latest emerging trends and technologies. An optional hands-on component is incorporated, contingent on participant preparation. To take part, please bring a Windows-based laptop without a firewall enabled, as access to the web-based PACS is currently not compatible with Mac systems. For optimal image review, we also recommend bringing a mouse for more precise navigation and interpretation.

W30 Stronger Together: The Fundamentals of Forensic Teamwork in Mass Disasters and Fatalities

Gina Londino-Smolar, EdD, IU Indianapolis, Indianapolis, IN; Beth Saucier Goodspeed, MS*, Lasell University, Bellingham, MA; Claire L. Glynn, PhD*, University of New Haven and Henry C. Lee Institute of Forensic Science, West Haven, CT; Lara Newell, MA*, Virginia Office of the Chief Medical Examiner, Richmond, VA; Megan Bassendale, MSc*, Forensic Guardians International, West Vancouver, British Columbia, Canada; Robert L. Hunkeler, III, MFS*, Montgomery County Coroner's Office, Xenia, OH; Jason W. Wills, DSc*, Jonesboro Fire Department, Jonesboro, AR; Khlea Sumani, DMD*; Scarlet Dental; Las Vegas, NV*

Learning Objectives: Attendees will: (1) identify the core roles and responsibilities of various forensic science disciplines and their interdependencies; (2) analyze case studies to understand how collaboration (or lack thereof) impacts case outcomes; (3) apply best practices for interdisciplinary communication and documentation; and (4) evaluate ethical challenges that arise in collaborative forensic work and propose solutions grounded in foundational principles.

Impact Statement: This workshop will have a significant and lasting impact on the forensic science community by reinforcing the foundational principle that forensic science does not operate in isolation. By bringing together professionals from across the forensic, investigative, and legal spectrum, this workshop will foster a deeper understanding of how collaboration enhances the accuracy, efficiency, and ethical integrity of forensic casework. Participants will gain practical tools to improve communication, streamline workflows, and resolve conflicts that often arise in multidisciplinary environments. This workshop will also promote a culture of mutual respect and shared responsibility, which is essential for maintaining public trust in forensic outcomes and the justice system as a whole. By returning to the basics of teamwork, ethical practice, and scientific rigor, this workshop will help reestablish a common language and purpose among forensic professionals. It will inspire a new generation of practitioners to prioritize collaboration as a core competency, ultimately leading to more robust investigations, fairer trials, and stronger communities.

Abstract Text: This workshop will explore the essential yet often complex collaboration between forensic scientists, law enforcement, and the justice system, in alignment with the 2026 AAFS theme. By revisiting the foundational principles of teamwork, communication, critical thinking, and scientific integrity, this session will highlight how interdisciplinary cooperation strengthens forensic casework and ensures justice.

A significant focus throughout the workshop will be on mass disasters, serving as a powerful lens through which to examine the intricate collaboration required across various forensic disciplines. Mass disaster scenarios, due to their scale and complexity, inherently demand seamless coordination and communication between all involved parties.

Participants will engage with real-world case studies that illuminate successful collaborative efforts and analyze instances where breakdowns in communication or teamwork impacted outcomes, particularly within mass disaster contexts. Discussions will delve into how diverse forensic disciplines—from anthropology and odontology to DNA analysis and toxicology—contribute to victim identification and evidence processing in such events.

Interactive panels will feature experts from forensic science, law enforcement, and the legal field sharing their perspectives on interdisciplinary challenges and solutions specific to mass disaster investigations. These discussions will cover establishing command centers, managing vast quantities of evidence, and coordinating international efforts when applicable.

Scenario-based exercises will challenge participants to apply foundational principles in simulated mass disaster events. Examples include:

- **Crime Scene Management in a Mass Fatality Incident:** Focusing on initial scene assessment, evidence collection, and body recovery in chaotic environments, emphasizing the roles of crime scene investigators, medical examiners, and first responders.
- **Victim Identification Challenges:** Simulating the process of identifying numerous victims through various forensic methods, highlighting the critical role of data sharing and inter-agency cooperation.
- **Courtroom Testimony in Mass Casualty Events:** Practicing how to clearly and ethically present complex scientific findings from a mass disaster investigation to a jury, ensuring that the collaborative effort behind the findings is effectively communicated. Emphasis will be placed on ethical decision-making, navigating complex ethical considerations that arise, particularly under the high-stakes and emotionally charged conditions of a mass disaster. The paramount importance of meticulous chain of custody protocols will be reinforced, especially when dealing with a large volume of evidence and samples. Finally, developing strategies for clear communication across professional boundaries will be a core component, fostering effective communication between diverse professional groups through standardized terminology and established channels. By integrating mass disaster scenarios, this workshop will powerfully demonstrate how "back to basics" principles are indispensable for achieving accurate and just outcomes in challenging forensic investigations.

W34 A Skeletal Atlas of Elder Abuse II—Beta-Testing a Revised Digital Diagnostic and Educational Tool

Katelyn L. Bolhofner, PhD, Arizona State University, Phoenix, AZ; Kevin A. Gary, PhD*, Arizona State University, Mesa, AZ; Jane E. Buikstra, PhD*, Arizona State University, Tempe, AZ; Jacob A. Harris, PhD*, Arizona State University, Phoenix, AZ; Laura C. Fulginiti, PhD*, Clark County Office of the Coroner/Medical Examiner, Mesa, AZ; Uma Nallamilli, BS Arizona State University Mesa, AZ; Shreya Prakash, BS Arizona State University Mesa, AZ*

Learning Objectives: After attending this workshop, attendees will be able to: (1) describe methods used to characterize assess skeletal fracture patterns in elderly individuals and the ways in which aging affects fracture and recovery; (2) understand there are different patterns of trauma associated with abuse/neglect and with accidental falls, (3) understand how to navigate the presented digital atlas of elder abuse, both for educational and diagnostic purposes; and (4) participate in beta testing the atlas and contribute usability data toward its final construction.

Impact Statement: Ten percent of adults aged 65+ will experience some form of abuse annually. Physical abuse and caregiver neglect account for most cases, yet remain difficult to prove. Skeletal expressions of abuse offer key indications of inflicted and untreated injuries, but are masked by assignation to accidental falls. Funded by the National Institute of Justice (NIJ), our research aims to produce a standard for the diagnosis of elder abuse in the skeletal system. This presentation will impact the forensic science community by offering a user-reviewed and expert-revised version of a digital tool for diagnosis and education so that we may improve our understanding of fractures and their contexts in elderly individuals.

Abstract Text: Increasing rates of elder abuse in the United States over the past few decades have produced an urgent need for improved diagnostic criteria to better design intervention procedures, to implement recognition criteria, and to achieve justice for victims. Physical abuse of elders represents the most severe manifestation of this trend, yet it is difficult to prove and may be masked by attribution of injury to medication or accident. In our 2025 AAFS workshop, attendees were introduced to the first complete iteration of the Skeletal Atlas of Elder Abuse—A Digital Tool for Diagnosis and Education and provided invaluable feedback for its continued revision. In this follow-up workshop, attendees will be introduced to the revised tool and asked to participate in further beta testing in anticipation of its official launch. Attendees need not have attended the 2025 workshop to engage. Presenters will review how aging impacts skeletal trauma incidence and patterning and will provide an overview of differences in the skeletal patterns of injury between accidental falls and cases of abuse/neglect uncovered in our NIJ-funded research as well as the impact of bone density loss on these patterns. The presenters will discuss the continued development of the online platform, the results of participant-guided revisions over the past year, and will request attendee feedback through further beta testing of the site. Participants will have the opportunity to hear updates from the developers of the machine learning and AI models driving the diagnostics of the site as well as from the software development team responsible for the creation of the atlas. This workshop probes the opportunities and challenges associated with the development of such a tool, asking attendees for participation, suggestions, interaction, and user-experience measures.

Skeletal Fractures; Elder Abuse; Digital Atlas

W35 The Medicolegal Investigation of Recreational Diving Fatalities

James L. Caruso, MD, Office of the Medical Examiner, Denver, CO; Craig Nelson, MD*, Office of the Medical Examiner, Raleigh, NC; Andrea Zaferes, MFS*, Dutchess County Medical Examiner's Office/FACT, Shokan, NY; Frauke Tillmans, PhD*, Divers Alert Network, Durham, NC*

Learning Objectives: Attendees at this workshop will: (1) gain an appreciation for the number of diving-related deaths that occur each year, the most common causes of death and contributing factors, and how that data is collected; (2) learn best practices in the investigation of recreational diving fatalities and deaths due to drowning; (3) attain a basic understanding of diving physiology and pathophysiology; (4) appreciate that there are certain techniques that can be utilized to maximize the information obtained from the postmortem examination of SCUBA diving deaths and deaths suspected to be due to drowning: (5) know how to interpret the findings of a postmortem examination of someone who died while breathing compressed gas under pressure; and (6) have references and resources that can be used when faced with investigating recreational diving deaths

Impact Statement: This presentation will impact the forensic community by providing the training and resources needed to forensic pathologists, medicolegal death investigators, attorneys, and members of law enforcement agencies so they may competently and confidently investigate recreational diving-related deaths.

Abstract Text: The popularity of recreational diving using Self-Contained Underwater Breathing Apparatus (SCUBA) has increased dramatically over the past several decades. Estimates place the number of active recreational divers in the world at between 6 and 9 million. Popular dive sites are located in the Mediterranean, Red Sea, Caribbean, South Pacific, Australia, Southeast Asia, and other locations worldwide. Diving-related fatalities, while fortunately uncommon, are not rare events (an average of 80 to 90/year in North America). These fatalities challenge the medicolegal death investigators and pathologists who must investigate and certify these deaths. Recreational diving fatalities are often litigated in civil court. This workshop is designed for pathologists, death investigators, attorneys, and law enforcement personnel who may be tasked with investigating a SCUBA diving accident or fatality. The initial portion of the workshop will include a brief overview of diving physiology, including the effects on the body of breathing compressed gas at depth. The pathophysiology of barotrauma, nitrogen narcosis, oxygen toxicity, gas embolism, and decompression sickness (caisson disease) will be presented. The pathophysiology of drowning will be reviewed since it is a frequent final outcome in a fatal diving mishap. The epidemiology and risk factors associated with recreational diving fatalities will be presented. The recommended investigation of a fatal diving mishap will be discussed using illustrative cases from several jurisdictions. The importance of interviewing witnesses and gathering information on the diver's past medical history, diving experience, pre-dive status, and the circumstances surrounding the dive will be emphasized. The relevance of knowing the exact depth and bottom time of the dive, as well as when and where the diver began to run into difficulty, will be discussed. The workshop will include a hands-on component, where diving equipment will be available for familiarization by attendees, accompanied by a brief discussion on the evaluation of dive gear. Not all water-related deaths are accidents; there will be a presentation on considering other manners of death. The final portion of the workshop will include a suggested autopsy protocol for SCUBA diving victims and emphasis on tests and observations that are helpful in determining the cause of death. The significance of finding intravascular bubbles will be discussed, with the proper interpretation of the autopsy findings. Natural diseases that are likely to cause sudden incapacitation and death while SCUBA diving will be reviewed. Thorough handouts will be provided, including checklists of important information to obtain, a diving fatality reporting form, a suggested autopsy protocol for use on a diving-related fatality, and recommended resources for consultation and referral. Attendees will leave the workshop with a better understanding of diving physiology, the drowning process, the equipment used in recreational diving, the epidemiology of diving-related deaths, and the special techniques that can be employed during the investigation and autopsy of these deaths.

SCUBA Diving; Drowning; Death Investigation

A1 A Comparative Analysis of Different Maceration Techniques and Their Effects on Bone Integrity

Emily Mahoney, George Mason University, Fairfax, VA; Chloe R. Cummings, BS, George Mason University, Fairfax, VA; An-Di Yim, PhD, George Mason University, Manassas, VA*

Learning Objectives: After attending this presentation, attendees will understand how various maceration techniques affect bone integrity and vary in level of efficiency. Through a comparative analysis that includes Alternate Light Source (ALS) imaging and microscopic evaluation, they will be able to identify the most effective and least damaging method for the preparation of skeletal remains.

Impact Statement: This presentation will impact the forensic science community by providing attendees with a deeper understanding of the effect of maceration on bone integrity. This allows for the identification of techniques that are able to effectively remove soft tissue from bone without causing damage to the bone. Novel techniques such as the steam kettle and the pressure cooker are tested for the first time and their effects analyzed.

Abstract Text: In forensic anthropology, skeletal remains are analyzed to construct a biological profile of the deceased, aiding in identification and understanding the circumstances surrounding death. When remains are not fully skeletonized, maceration is performed to remove soft tissue from the bone surfaces to facilitate analysis and long-term preservation of the remains.[1] Various maceration methods exist, many of which can damage bone. When selecting a maceration method, it is important to minimize postmortem alterations and preserve the integrity of the skeletal remains.[2] The goal of this study is to compare how different maceration methods affect bone integrity in order to identify a technique that is efficient and least damaging.

In this study, six different maceration techniques (hot water with detergent, cold water, bleach, microwave, steaming, and pressure cooking) were performed on 12 porcine bones, with one humerus or tibia and one scapula assigned to each method. Following treatment, bones were dried at 25°C for approximately 48 hours. Each bone was weighed before and after treatment, and the treatment duration for each method was documented. Bone damage was evaluated through visual assessment and microscopic examination using a digital stereomicroscope, and an ALS was utilized to further assess and quantify damage, including changes in optical properties. This was done by visualizing fluorescence under a 450nm blue light and applying the Lux Fire photo filter in the ImageJ software, which applies a color map to visualize intensity levels of the fluorescence.

The results showed that while all treatments resulted in a decrease in bone weight due to tissue removal, the differences between treatments were not statistically significant ($p = 0.1321$, Kruskal-Wallis test). Cold water and microwave treatments caused the least observable damage but were largely ineffective, leaving the bones greasy and odorous. The hot water and detergent method successfully removed all material and grease from the bones, but minor flaking of the outer bone layer in the prominent regions, such as the neck of the humerus and the spine of the scapula. Bleaching, while effective at cleaning, resulted in significant microscopic damage and discoloration, rendering it unsuitable for forensic purposes. Pressure cooking also caused some discoloration to the outer edges of the bone and minor flaking of the bony prominence. While moderately effective, it was less successful than the hot water and detergent method. Steaming produced both macro- and microscopic damage and was the least effective of all the methods.

This study demonstrated that hot water with detergent was the most effective maceration method out of all the methods tested. The use of ALS imaging proved valuable for detecting subtle bone surface damage that is not easily visible to the unaided eye. Notably, bleach caused marked changes in the optical properties of bone, an important factor to consider when interpreting ALS findings in forensic investigations.

A2 The Effects of Basic Solution Concentration and Bone Tissue Type on Progressive Decomposition Solution Color and Clarity

Kendall Gehring, MA, California State University, Chico, Grayslake, IL*

Learning Objectives: This poster will present experimental results from a study comparing the solubilization of biological matter from both cortical and trabecular porcine bone samples in concentrated and diluted basic corrosive solutions.

Impact Statement: After viewing this presentation, attendees will gain a better understanding of the interactions between basic corrosive substances and skeletal tissues. The preservative properties of basic compounds will be explored in the context of submerged tissues, which may inform both skeletal recovery techniques and future anthropological analyses.

Abstract Text: Basic corrosive substances are known to have extended preservative effects on biological tissues, rather than the degradative properties often associated with acidic corrosives.[1] Previously published comparisons of the effects of different solutions on bone tissue have demonstrated that characteristics such as solution color and clarity will vary depending on the submersion environment's pH, ranging from a pale yellow solution in bases to a dark reddish-brown for acidic ones.[2] The aim of this study was to make two comparisons of the residual solution color and clarity following sample submersion. It was hypothesized that an increase in the concentration of the active ingredients would augment the preservative properties of the solution, leading to a lighter solution with preserved tissue pieces at the bottom of the sample jar. It was also hypothesized that the more porous trabecular microstructure would allow greater interaction between the solution and sample, leading to a more rapid preservation of tissue.

Two solutions were prepared using an industrial strength drain cleaner with active ingredients sodium hydroxide and sodium hypochlorite; one solution was concentrated, and one was diluted. Twenty-two porcine samples, 11 cortical and 11 trabecular, were submerged in each solution. Cortical and trabecular tissues were separated as differing microstructures in each type of bone provide variable bone surface area; this allows for more interaction with the corrosive solutions in trabecular bone samples than in cortical bone samples. Samples were photographed at intervals ranging from 30 minutes after submersion to 7 days after submersion. Solution color was determined using the software ImageJ and a slight modification of a previously published method.[3]

Average solution color was compared between concentrated and dilute basic trials using a Student's *t*-test at each photo interval. Statistical significance was found in six intervals: 4 hours ($p = 0.030$), 8 hours ($p = 0.005$), 12 hours ($p = 0.002$), 24 hours ($p < 0.001$), 4 days ($p = 0.042$), and 6 days ($p = 0.021$). As predicted, the samples exposed to the concentrated solution retained a lighter solution color than the samples exposed to the dilute solution, as biological tissues were preserved and fluids fixed in place. While trabecular samples did allow greater immediate exchange between samples and solutions, this caused a quicker solubilization of blood retained in the epiphyses, which was observed in the much darker solutions for the trabecular samples than the cortical ones. Trabecular samples exposed to the concentrated solution reached a final dark yellow color, while trabecular samples exposed to the dilute solution were very dark red by the seventh day. The results of this study confirm that a solution with a greater concentration of active ingredients with known preservative properties will result in better preservation of osseous remains, and that solution color and clarity differ relative to the strength of corrosive compound when skeletal materials have been submerged in unknown chemical solutions.

A3 The Impact of Standard Forensic Processing Practices on the Accuracy of Dental Age Estimation Methods

Chloe Yingling, BS, Mercyhurst University, Erie, PA; McCarthy Lang, BS, Mercyhurst University, Erie, PA; Luis L. Cabo, MS, Mercyhurst University, Erie, PA;Joe Adserias-Garriga, PhD, Mercyhurst University, Erie, PA;Cheyenne Hindman, MS, Mercyhurst University, Erie, PA*

Learning Objectives: Attendees to this presentation will improve their understanding of the effects of high and low temperatures on the ability to estimate age accurately, using widely accepted dental age estimation methods.

Impact Statement: This presentation will impact the forensic science community by providing additional information on the potential effects of forensic processing methods, such as heated maceration, on some widely utilized adult dental age markers and methods. To our knowledge, this is the only project that explores the effects of processing temperatures on age estimation markers and methods.

Abstract Text: Dental age estimation based on tooth growth and development is standard for subadults.[1] However, adult methods are less predictable and yield broader age ranges.[2] This study focuses on secondary dentin apposition and root translucency, two of the most reliable post-formation age indicators.[2-4]

Secondary dentin apposition reduces the pulp cavity from crown to apex, which is observable in radiographs.[5,6] Root translucency begins at the apex and extends coronally due to peritubular dentin deposits of hydroxyapatite altering the refractive index.[7,8]

In forensic practice, remains may be exposed to high heat or low temperatures during recovery, processing, or storage. Odontological analysis typically occurs after such exposures. This study continues previous work on temperature effects on dental age markers.[2] Forty-one permanent upper and lower canines were processed in hot water (52°C) and freezing temperatures (-4°C) for different times. Translucency and pulp area were measured before and after treatments.

Although repeated-measurements via Analyses of Variance (ANOVAs) with Geisser-Greenhouse correction for heteroskedasticity (sphericity) did not reveal any changes in average root translucency with hot water maceration, the time groups were heteroskedastic under that treatment, with translucency dispersion increasing with treatment time. In contrast, root translucency did decrease significantly with freezer storage time ($F_{2.521, 47.9} = 8.328$; $P < 0.001$). More specifically, the difference became significant after five days of freezer storage (Dunnett's T3 post-hoc test; $q_{19} = 4.296$; $P < 0.001$). Conversely, pulp area dimensions decreased over time only at high temperatures ($F_{2.148, 40.8} = 8.328$; $P < 0.001$), with the difference becoming significant after just 24hrs ($q_{19} = 5.777$; $P < 0.001$). However, whether these dimensional changes are large enough to affect age estimation accuracy remained unclear.

To address this question, pulp dimensions and root translucency measurements were applied into the age estimation formulae, and the estimates compared to the chronological ages of the individuals through mean comparisons of the observed errors and frequency tests of the accuracies obtained at different treatment times. Our results show that age estimations from root translucency-based methods are minimally affected by the observed temperature-induced changes, while pulp-based age estimations can be more affected by both heat and cold treatments.

A4 Flesh to Bone: Time-to-Skeletonization Using *D. Maculatus* in a Forensic Anthropology Laboratory

Gage C. Papp, BS, Florida Gulf Coast University Human Identification and Trauma Analysis Laboratory, Lehigh Acres, FL; Micki Besse, MS, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University, Fort Myers, FL;Savanna Agilar, MS, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Joyce Fassbender, PhD, Florida Gulf Coast University, Fort Myers, FL*

Learning Objectives: After this presentation, attendees will understand skeletonization rates for six human body regions that decomposed within a controlled laboratory environment using three *Dermestes maculatus* (*D. maculatus*) colonies maintained by the Human Identity and Trauma Analysis (HITA) laboratory at the Emergent Technologies Institute at Florida Gulf Coast University (FGCU). This study more broadly examines rates of decomposition across six anatomical regions (skull, thorax, pelvis, upper extremity, lower extremity, and hands/feet) using a mean temperature of 23.3°C (74°F). This work also highlights a back-to-basics approach to skeletal rendering for anatomical gift donation programs that can be traced to early taxidermy and museum rendering in the United States and abroad.

Impact Statement: This research impacts the forensic science community by evaluating the time to skeletonization evaluated using six body regions (skull, thorax, pelvis, upper extremity, lower extremity, and hands/feet) using *D. maculatus* colonies in a forensic anthropology laboratory by linking current practices to methods established over a century ago in museum and taxidermy settings.

Abstract Text: Since the 19th century, natural science museums, including the Smithsonian Institution, and taxidermists used *Dermestes maculatus* (*D. maculatus*; hide or flesh-eating beetles; Family: Dermestidae) to skeletonize human and non-human remains.[1] This technique represents a minimally destructive alternative to maceration and other laboratory-based processing methods; although maceration may follow processing to remove fat and persistent soft tissue. Researchers consider *D. maculatus* processing to be: (1) less destructive to bone (except when starved larvae bore into bone to create pupal chambers); (2) more efficient, as colonies require monitoring rather than active rendering; and (3) DNA-safe.[2-4] While adult beetles consume desiccated or mummified tissue, larvae rapidly ingest soft tissue, making colonies highly efficient for defleshing rather quickly.[5] Prior research demonstrated that *D. maculatus* skeletonized sectioned Burmese python (*Python bivittatus*) remains (approximately 14kg; human-arm equivalent) within 24–48 hours.[6] Similar studies indicated rodent skeletonization in nearly 48 hours, whereas larger mammals (i.e., deer) took nearly one week to skeletonize.[7]

This study examined skeletonization time of incomplete adult human anatomical gift donations (n = 45) using three *D. maculatus* colonies in the Florida Gulf Coast University Human Identity and Trauma Analysis (FGCU HITA) Laboratory. Colonies were maintained in glass aquariums (3.913–4.27ft³) with wood-based substrate, Zoo-Med ReptiTherm adhesive heating pads, and ThermPro humidity and temperature sensor beneath a 14-foot fume hood for odor abatement and control of 23.3°C (74°F) and 65% humidity. Anatomical regions were placed into the colonies and removed upon skeletonization. An inventory of the fleshed skeletal elements placed into the tanks and processing time were documented following standardized protocols and analyzed in IBM SPSS Statistical Analysis Software. This study hypothesized that greater quantities of elements would decompose slower in *D. maculatus* colonies irrespective of mass.

An average of 49 fleshed skeletal elements were placed into each colony with skeletonization occurring within six days on average. A significant positive correlation was observed between the number of elements placed in the colony and the total processing time ($r = 0.439$, $p = 0.001$), supporting the hypothesis that higher quantities of remains decomposed slower within the colonies irrespective of mass. Among anatomical regions, the thorax (ribs, clavicles, scapulae, and vertebrae; n = 36) was most frequently processed, followed by hand and foot elements (n = 28), lower extremities (n = 24), pelvis (n = 19), upper extremities (n = 16), and skull (n = 9). Skeletonization naturally begins in superior anatomical regions and progresses inferiorly during decomposition, creating variation in the frequency of processing between regions. The thorax had the longest average processing time (11.1 days), followed by the lower extremities (8.25 days), upper extremities (8 days), hand and foot elements (7.68 days), the pelvis (6.9 days), and skull (6.72 days). The hyoid, thyroid cartilage, and cricoid cartilage were never processed due to their fragility. These findings supported the use of *D. maculatus* colonies as a safe, effective, and minimally destructive method for human remains processing in forensic anthropology laboratories. This research provides baseline skeletonization timeframes under controlled laboratory conditions and reinforces the utility of *D. maculatus* in modern forensic contexts.

A5 Pore Extractor 2D v. 2.0: New Utilities for Mapping Collagen Fiber Orientation and Cortical Pore Distribution

Mary E. Cole, PhD, The Ohio State University, Columbus, OH; Emma T. Brzezinski, MA, The Ohio State University, Columbus, OH; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH*

Learning Objectives: After attending this presentation, attendees will understand the forensic applications of quantifying collagen fiber orientation and cortical pore distribution through histological analysis of bone tissue.

Impact Statement: This presentation will impact the forensic science community by providing new image processing tools for automated, reproducible analyses of metrics related to bone quality, fragility, and mechanical properties.

Abstract Text: Quantifying cortical porosity in bone tissue can inform forensic interpretations of skeletal trauma, age-at-death, and bone quality and fragility. To expedite this analysis for histological images, we previously developed Pore Extractor 2D, a macro toolkit for the open-source software ImageJ.[1] Its initial release included tools for cleaning cortical borders, image contrast and noise removal, computer-assisted isolation of probable pore spaces, keyboard shortcuts for manual correction, and automated regional analyses of pore type and morphometry.

This new release, Pore Extractor 2D v. 2.0, updates these tools for subpixel resolution in current installations of ImageJ, where freehand border correction can split individual pixels. This ensures the reproducibility of morphological measurements at lower image magnifications.

Additional tools developed for this release include:

- CFOTool: provides regional analysis and visual mapping of Collagen Fiber Orientation (CFO) for histological images viewed under Circularly Polarized Light (CPL). CFO is thought to correspond to bone mechanical properties, resulting from localized adaptations to mechanical demand. Collagen fibers oriented transverse to the plane of section are better adapted to resist compression and appear brighter under CPL. Collagen fibers oriented longitudinal to the plane of section are better adapted to resist tension and appear darker under CPL. This analysis has forensic potential to assist with orienting cross-sections, inferring mechanical loading history, and identifying regions of localized weakness. The predominant CFO of a tissue region can be quantified using Weighted Mean Gray Level (WMGL), which is the sum of pixel gray levels each weighted by their fraction of pixels in the region.[2] CFOTool fully automates this analysis by providing WMGL for whole cross-sections, user-selected regions, or automatically generated anatomical quadrants (long bones) or cutaneous and pleural cortices (ribs). CFOTool also allows the user to remove pore spaces from this calculation, either by excluding a gray level range of dark pixels, or by loading the pore regions-of-interest produced through the Pore Extractor 2D workflow.[2] A colormap of pixel-level brightness is also generated to visualize collagen fiber orientation throughout the cross-section.[3]

- Cortical Pore Score: calculates the cumulative effect of pore size and pore spatial distribution. Pores located further from the section centroid have a greater effect on bone strength, such that wider bones are weakened by porosity more than narrow bones. External bone size has been shown to influence patterns of age-associated bone loss to porosity.[4] Quantifying this effect has forensic potential to inform assessments of bone fragility and apparent age-at-death. Cortical pore scores are calculated relative to the section centroid, anatomical axes, and major/minor axes, and as a percent change in the area moments of inertia about these axes compared the solid cross-section.[4] Users have the option to calculate this cross-sectional geometry from this tool's integrated Moment Macro, or to use ImageJ-integrated BoneJ for additional pixel moment correction, exporting their associated naming conventions.

Histological analysis remains the gold standard for visualizing relationships between these microstructural components of bone tissue. Image analysis tools improve the accessibility and reproducibility of histological techniques within forensic anthropology.

A6 Investigating the Position and Morphology of the Mental Foramen for Sex Estimation

Natalie S. Wise, MA, University of South Florida / FL Institute of Forensic Anthropology & Applied Science, Tampa, FL; Erin H. Kimmerle, PhD, University of South Florida / FL Institute of Forensic Anthropology & Applied Science, Tampa, FL*

Learning Objectives: The aim of this presentation is to explore metric and morphoscopic variables of the Mental Foramen (MF) for the purpose of sex estimation. The MF is understood to be sexually dimorphic by practitioners outside of the United States, yet this landmark has not been evaluated as a reliable mandibular variable within American forensic research. The present research serves as an introductory exploration of sexual dimorphism from the position and morphology of the MF in a modern donated skeletal collection.

Impact Statement: This presentation will impact all forensic anthropologists and odontologists who utilize the mandible for biological profile estimation. The mandible becomes a critical element in sex estimation when the cranium and pelvis are not available for analysis due to damage or postmortem loss. By adding more variables to mandibular data collection protocols, practitioners are able to further quantify sex estimation from this skeletal element.

Abstract Text: The mandible provides reliable metric and morphoscopic features for sex and ancestry estimation of unidentified skeletal remains. In research conducted outside of the United States, the distance of the MF on the mandibular body to the lower border of the mandible and to the alveolar crest, the position of the foramen in relation to the dentition, and the shape of the foramen have been utilized as variables for sex estimation. The hypothesis that the MF is sexually dimorphic has been tested on various populations, including Indian, Malaysian, Chinese, South African, European, and other populations from both dry bone and radiographs.[1-8] These studies demonstrate that the MF is a stable landmark on the mandible that does not change with age nor dentulous status, therefore making the position and morphology of the MF reliable. However, these studies lack consistency of measurement location, where different margins of the MF have been used to document distance to the lower border of the mandible and to the alveolar crest, and it has observed that alveolar resorption does affect the position of the mental foramen in edentulous individuals.

This presentation investigates the sexual dimorphism of the position and shape of the MF and attempts to establish consistency in measurement location. The test sample consists of 60 dentulous mandibles, with equal quantities of males and females, from the University of South Florida (USF) Donated Skeletal Collection, housed at the University of South Florida in Tampa, FL. Data were collected by recording the distance between the superior margin of the MF to the lower border of the mandible (SM-LBM), inferior margin of the MF to the lower border of the mandible (IM-LBM), superior margin of the MF to the alveolar crest (SM-AC), medial margin of the MF to the mandibular symphysis (MM-MS), shape of the MF (round or oval), and the position of the MF relative to the dentition.[6] The data were analyzed using multiple quantitative methods to establish the sexual dimorphism of the MF position and morphology in a modern United States population.

The results show that there are statistically significant differences between males and females for SM-LBM (t=3.534, p=< 0.001), IM-LBM (t=2.279, p=0.026), and MM-MS (t=2.300, p=0.025). These variables point to sexual dimorphism of the position of the MF in relation to lower border of the mandible and to the mandibular symphysis. There is not a significant difference between males and females for SM-AC (t=1.657, p=0.103), shape of the MF ($c^2 = 3.455$, $p = 0.063$), or position of the MF in relation to the dentition (p=0.575). This indicates that the morphology of the MF and its relative location to the teeth are not sexually dimorphic. Additional research to investigate the role of population variation of the position of the MF to the lower border of the mandible and to the mandibular symphysis may further emphasize this landmark as an important feature for use in biological profile estimation from the mandible.

A7 Exploring Cranial Morphological Variation Within Operation Identification Cases Using 3D Surface Geometric Morphometrics

Rebekah T. Stowe, MA, Texas State University, San Marcos, TX; Kate Spradley, PhD, Forensic Anthropology Center at Texas State University, San Marcos, TX; Nicholas P. Herrmann, PhD, Texas State University, San Marcos, TX; Elaine Y. Chu, PhD, Texas State University, San Marcos, TX*

Learning Objectives: After this presentation, attendees will better understand the cranial variation within identified and unidentified Operation Identification (OpID) cases, including how this relates to the country of origin. Attendees will also learn about creating 3D homologous models and their potential use in cranial morphology research to expand upon previous methods and datasets.

Impact Statement: This research expands the anthropological knowledge of migrant cranial variation along the South Texas border. It also exemplifies how basic ideas of cranial variation (and therefore population affinity) can be revisited using increasingly popular technological and statistical advances through 3D surface scans and the creation of homologous models highlighting areas and patterns of variation often left underrepresented by traditional methods.

Abstract Text: Forensic anthropological analyses typically begin with building a biological profile that includes population affinity, which is the probability of group membership based on similarity to well-defined reference groups.[1] In migrant death contexts along the United States-Mexico border, these estimates are often limited to a broad term of "Hispanic."[2-4] For organizations like OpID at Texas State University, to identify and repatriate such individuals, determining a more specific region of origin is crucial to connect with consulates and Non-Governmental Organizations (NGOs) for comparisons to missing persons, particularly in historically marginalized communities.[2-4]

Commonly used population affinity estimation methods, such as FORDISC and other biological affinity software, rely on static two-dimensional Interlandmark Distances (ILDs), 3D landmark coordinates, or the scoring of discrete morphological traits.[5] All of which, by nature, leave out significant morphological data. With the rise of affordable 3D surface scanners, researchers can now collect more comprehensive cranial morphology data.

This research broadens understanding of the cranial variation within a sample of OpID cases using 3D homologous models. To do so, 37 crania from OpID cases (16 with identifications and known regions of origin: Mexico, Honduras, El Salvador, and Guatemala) were scanned using a high-resolution blue light scanner. The scans were input into the HBM-Rugle software, where they were fit to a simplified cranium template using 56 biological landmarks in an iterative closest point algorithm.[6] The template was deformed to each target mesh to ensure all meshes had the same number of vertices (17,709) with the same spatial arrangement while retaining the target's geometry. While only the landmarks have true biologically defined homology, the template fitting technique creates practically homologous models[7].

A Principal Component Analysis (PCA) was run on the identified homologous models to reduce dimensionality and investigate morphological variation. The unidentified individuals were then placed within the principal component analysis to see how they compared. Fourteen principal components captured 99.25% of the variance within the identified. The first three principal components captured 61.74% cumulative variance, primarily representing overall size and marked cranial vault asymmetry for PC1, length-width changes for PC2, and height-width changes for PC3. In addition, more subtle, focal asymmetry is represented in PCs 2 and 3.

Results showed considerable overlap among the countries of origin within the PCA, which demonstrates no simple path to clustering for population affinity. However, numerous notable trends were observable, such as all identified Mexican individuals exhibiting similar size and lack of asymmetry. Additional trends arose when comparing unidentified individuals, as they were typically smaller overall and longer rather than wider in the vault than identified individuals.

This research demonstrates the potential for 3D homologous models to be incorporated into cranial variation research. The results highlight significant areas of variation, particularly along the vault, that are underrepresented in traditional population affinity estimation methods. The homologous model method also provides directionality and relationships between cranial areas that traditional ILDs and simple landmark-based geometric morphometrics do not. The creation of this dataset aids in expanding global cranial reference data for future population affinity estimation techniques.

A8 Testing Approaches to Population Affinity/Sex Classification Using FORDISC 3.1: Considerations for Best Practice Recommendations for United States Forensic Casework

Alexandra R. Klales, PhD, Washburn University, Topeka, KS; Kate M. Lesciotto, PhD, University of North Texas Health Science Center, Fort Worth, TX*

Learning Objectives: The goal of this presentation is to inform attendees about several methodological approaches for using the program FORDISC 3.1 (FD3.1) and to test which of these approaches is most appropriate (i.e., the most valid) for forensic anthropological casework in the United States.

Impact Statement: This presentation will impact the forensic science community by providing recommendations for the application of FD3.1 and results in casework. These recommendations can guide standards development in the field and ultimately result in best practice recommendations for population affinity estimation in forensic anthropology.

Abstract Text: When estimating the biological profile of an unknown decedent population affinity is usually estimated prior to or simultaneously with skeletal sex as the degree of sexual dimorphism has been documented to vary across groups. The software FD3.1 is the preferred quantitative method of estimating population affinity. The FD3.1 helpfile includes guidelines that describe two different approaches to population affinity estimation using craniometrics. The first approach involves estimating population affinity simultaneously with sex by including all 13 available Forensic Databank (FDB) reference samples with males and females from multiple groups ("Simultaneous Sex & Population Affinity Approach/SSPAA"). The second approach involves using only the male or female FDB reference groups, based on an *a priori* indicator of sex ("Population Affinity Only Approach/PAOA"). Jantz and Ousley further recommend reducing the initially included FDB reference samples iteratively until only four ("4-way") to two ("2-way") groups remain for the final classification of the unknown individual.[1] A recent publication demonstrates that both recommended approaches are utilized for population affinity estimation; however, to date, no research has compared the two approaches or using a 4-way versus a 2-way for the final classification.

Using craniometric data of a known sample including Black, Hispanic, and White males and females (n=130) from multiple modern United States skeletal collections, this research tested both approaches and the 4-way versus 2-way group reduction to set forth recommendations for United States forensic casework. For the PAOA, sex was estimated qualitatively using ordinally scored cranial features and the MorphoPASSE program. The sex estimate produced by MorphoPASSE, regardless of posterior probability, dictated which FDB reference samples were included in the analysis.

Accuracy was highest using the SSPAA and a 4-way final classification. In this approach, the population affinity/sex group was correctly predicted in 64.6% of cases (i.e., matched the known demographics of the decedent). For 40.5% of misclassified individuals in this analytical approach, the correct population affinity/sex was the second most similar group based on the Mahalanobis Distance in FD3.1, and in 66.7% of misclassified individuals, the correct population affinity/sex was one of the three remaining reference groups. These results indicate that FD3.1 is highly inclusive of the correct population affinity/sex group in the final output when using all 13 FD3 craniometric reference samples and reducing the final comparison to four groups. Accuracy was slightly lower (60.8% correct) using the SAPAA and a 2-way final classification, and for the misclassified individuals, only 40.8% had the correct population affinity/sex as the second most similar group. Accuracy was overall lower with the PAOA (60.0% 4-way; 62.3% 2-way).

These findings suggest that FORDISC 3.1 should be utilized in its full capacity for combined population affinity/sex estimation by including all 13 available FD3 reference samples when using craniometrics, rather than relying on qualitative methods for *a priori* sex estimation. The final estimate should be based on a reduction to four classification groups and care should be given to determine if the unknown individual is similar to the remaining groups into which it did not classify.

A9 Comparing the Utility of 3-D Photogrammetry Models and Casts in Forensic Anthropology

Lauren A. Keith, BS, Texas State University, San Marcos, TX; Hailee M. Desrosier, MS, Michigan State University, Lansing, MI; Carolyn V. Isaac, PhD, Michigan State University, East Lansing, MI; Joseph T. Hefner, PhD, Michigan State University, East Lansing, MI*

Learning Objectives: After attending this presentation, attendees will learn how the use of casts, photogrammetry models, and real bone impacts observer variability when assessing skeletal age and sex indicators. Additionally, attendees will learn which of these modalities more closely approximates real bone quantitatively.

Impact Statement: This presentation will impact the forensic anthropological community by allowing members to make informed decisions concerning the use of casts, photogrammetry models, and real bones for research, teaching, training, and testing purposes.

Abstract Text: Casts and virtual 3-D models of bones have been used for education, testing, and training in forensic anthropology for accessibility and ethical reasons; however, there has been little documentation on which modality is most useful, specifically for age and sex indicators in the pelvis. This study compares age and sex indicator assessments between casts, 3-D photogrammetry models, and real bone to determine suitability for institutional and student use. Additionally, this study quantitatively compares the three modalities in virtual 3-D representations to determine if there are inconsistencies between replicas and real bone.

Seven donors with complete left and right ossa coxae from the Michigan State University Forensic Anthropology Laboratory Donated Skeletal Collection were selected to create casts and 3-D photogrammetry models of the pubis for comparison. Fourteen observers, ranging in education level, assessed indicators of age (Hartnett method) and sex (Klales et al. method) independently on the three modalities.[1,2] Mixed-effects models, post hoc pairwise comparisons, and Analysis Of Variance (ANOVA) were used to analyze the effects of modality and experience level on observer assessments. The casts and photogrammetry models were quantitatively compared in MeshLab utilizing Hausdorff distances and paired t-tests were used to analyze statistical significance.[3]

There were no significant differences in age and sex indicator scores by observers between modalities ($p > 0.05$). There were also no significant differences in results based on experience level. However, the Hausdorff distance comparison within MeshLab shows the casts more closely replicate the bones than the photogrammetry models; paired t-tests of the Hausdorff distances of bone-cast versus bone-photogrammetry indicate significant differences ($p < 0.05$).

Since casts and photogrammetry models yield comparable results to real bone for age and sex indicator assessments, these replication methods are viable alternatives when real bone is not available. However, casts are preferred over photogrammetry models due to cost-efficiency, a tactile component, and because they more closely approximate real bone. Furthermore, the results of this study provide solutions to existing ethical concerns regarding teaching and data sharing. Understanding that casts and photogrammetry models perform similarly to real bone in observer analyses may allow institutions without access to skeletal collections to teach forensic anthropological methods without compromising the quality of education students receive. It should be noted, however, that some skeletal indicators (such as gross weight) cannot be assessed from casts and photogrammetry models. Nonetheless, the use of casts and photogrammetry models in education, research, and training may help mitigate the detrimental effects of consistent handling of human remains.

A10 Rethinking Variable Standardization: Why Mahalanobis Distance Does Not Require Normalized Craniometric Data

Joseph T. Hefner, PhD, Michigan State University, East Lansing, MI; Michael W. Kenyhercz, PhD, Phokus Analyica, Lakewood, OH*

Learning Objectives: After attending this presentation, attendees will be familiarized with how Mahalanobis distance inherently adjusts for variance and correlation in a dataset using the pooled within-group Variance/Covariance Matrix (VCVM), precluding the need for prior normalization of craniometric data when pooling sexes.

Impact Statement: This presentation will impact the forensic community by addressing the question of whether standardization of craniometric data is necessary prior to calculating Mahalanobis distances or applying those data to discriminant function analysis.

Abstract Text: Researchers often standardize skeletal data to address size-related differences or to equalize variable scales before applying multivariate statistics. This practice is common in Principal Components Analysis (PCA), Discriminant Function Analysis (DFA), and other ordination procedures where variables with differing magnitudes or scales have the potential to dominate an analysis. However, when Mahalanobis distance is used, this preprocessing step may be redundant and even counterproductive, obfuscating variable relationships.

We recently identified researchers advocating against standardizing data when using Mahalanobis distance (D^2) to evaluate multivariate differences.[1-6] They suggest doing so may distort meaningful biological relationships. This study demonstrates how Mahalanobis distance inherently adjusts for variance and intercorrelation using the VCVM.

Using craniometric data derived from the Forensic Anthropology Data Bank (FDB), we compare biological distances (D^2), Multidimensional Scaling plots (MDS), and classification accuracies derived from raw versus standardized variables. Our results suggest standardization only minimally alters group relationships, but, in doing so, potentially undermines the biological interpretability of Mahalanobis distances. MDS plots revealed altered group associations, including reduced distances between biologically dissimilar groups and increased distances between more closely related groups. These shifts demonstrate how standardization can distort the natural VCV structure preserved when raw data are used in an analysis.

To further quantify structural similarities in these datasets, we performed a Mantel test comparing the raw and standardized Mahalanobis distance matrices, which revealed a high correlation ($r = 0.914$), but a statistically significant difference ($p = 0.001$). Although the correlation between matrices indicates standardization can create structural alteration, the MDS goodness-of-fit and a series of Shepard diagrams favor the raw data, suggesting better preservation of the VCVM structure and maintenance of the inherent geometric relationships in morphology. For example, in the Shepard diagrams, observed distances aligned closely with fitted MDS distances, indicating low stress and strong preservation of the original (raw) matrix. In contrast, the standardized data exhibited greater vertical deviations, mirroring the goodness-of-fit (raw: 0.4614; standardized: 0.3694). A PCA performed on the same standardized dataset also favors the raw data. Although PCA and MDS are based on different principles (i.e., total variance versus distance structure), their outputs reveal near-identical ordination patterns, differing only by axis orientation and scaling. This is not surprising since Mahalanobis distance is approximating Euclidean distance in PCA space; both methods use transformations based on the correlation matrix. Finally, we performed standardization within components (neurocranium, splanchnocranium, etc.), preserving variable relationships within functional cranial units. This method offered a more biologically grounded approach, but it failed to preserve the full integrity of the original VCVM structure, reinforcing our argument against standardization.

Quantitative and visual comparisons consistently demonstrate standardizing data prior to calculating Mahalanobis distances is both unnecessary and potentially counterproductive. The Mahalanobis distance inherently accounts for scale *and* correlation via the pooled within-group VCVM, rendering prior normalization redundant. In other words, standardization meaningfully alters the matrix structure, but the converging lines of evidence support our central claim: *Mahalanobis distance should be computed on raw craniometric data to preserve biologically meaningful variation and ensure accurate group differentiation*.

A11 A Case Study: The Use of Interosseus Infusions in Adults and Resulting Skeletal Indicators

Kaleigh C. Best, PhD, Western Carolina University, Cullowhee, NC; Nicholas V. Passalacqua, PhD, The Ohio State University, Hilliard, OH*

Learning Objectives: The goal of this presentation is to present evidence of interosseous (IO) infusions in dry skeletal human remains, which could otherwise be a confounding defect for the analysis of trauma as well as the determination of medicolegal significance.

Impact Statement: This presentation will impact the forensic community by demonstrating how to differentiate modifications from IO infusions with other common defects found in human skeletal remains, including perimortem trauma and postmortem modifications.

Abstract Text: The examination of remains for perimortem trauma is a critical part of a forensic anthropologist's job, with the recognition of perimortem trauma being of upmost importance to medicolegal investigation. However, beyond standard classifications of trauma associated with cause or manner of death, the implementation of perimortem modifications from medical intervention should also be accounted for, as evidence of these procedures may be present in donated skeletal collections or among the medicolegal populations forensic anthropologists are called to investigate.

This poster represents a case study of a donor from Western Carolina University's (WCU) John A. Williams Human Skeletal Collection. During analysis, two small circular defects, approximately 2mm in diameter, in the anterior proximal aspect of both tibiae were observed. Margins of the holes were examined and appear sharp, perfectly round, and have similar coloration to the surrounding bone, all of which is consistent with perimortem trauma. No clear signs of blunt fracture or surrounding sharp injury were found on the tibiae. To investigate the cause of these holes, both skeletal analytical results and donor information were compared with common taphonomic modifications to human skeletal remains as well as the literature reflecting increase rates of IO use, selective placement of IO infusion sites.

In regard to postmortem modifications, insect holes, fat drainage during maceration, or mechanical drilling to facilitate anatomical specimens, may produce circular defects. In such cases, careful examination of the margins for regularity in circular shape, and color differentiation of the defect may assist in determining the relative timing of the cause of the modification. All circular defects in this case appear perfectly round with regular margins. Postmortem bone modifications both in the literature and in known comparative individuals housed at WCU demonstrate color changes, differences in cortical flaking around the margins of the defect, and differential taphonomic indicators on surrounding bone.

Of the various medical interventions implemented by medical professionals, since 2010, there has been a rise in the use of IO infusions rather than conventional intravenous access where life-saving medicine can be directly administered into the interosseus space.[1,2] IO infusions are performed by pressing a hollow bore needle through the skin, perpendicular to the surface of the bone, until the needle touches the bone surface. The needle is then either twisted or drilled through the cortex of the bone until it enters the medullary cavity so that infusions can be administered. While there are select number of spaces IO access can be established, the anterior proximal tibia is seen as advantageous due to its thin cortex and distance from other resuscitative efforts.[3-5]

This case study demonstrates that perimortem medical interventions may be present in skeletal remains which could be confused for other forms of skeletal modification. The misinterpretation of these defects could result in incorrect analytical conclusions, with broad implications for the outcome of a case. However, familiarity with updates to medical interventions and characteristics of osseous defects can assist in the determination of the origin of these defects.

A12 Assessing Potential for Individual Variation in Maxillary Sinuses and Mastoid Air Cells: Metric Size Components

Tayler R. Franklin, Western Carolina University, Richfield, NC; Kaleigh C. Best, PhD, Western Carolina University, Cullowhee, NC*

Learning Objectives: In this presentation, attendees will: (1) learn about how sinus development and etiology contribute to individualization potential; (2) examine maxillary sinuses and mastoid air cells for significant differences pertaining to sex and bilaterality; and (3) evaluate the potential use of these two sinuses for the applicability of sinus-pattern personal identification methods beyond frontal sinus personal identification approaches.

Impact Statement: Personal identification is one of many contributions offered via forensic anthropology analyses. While there is plentiful research on personal identification methods utilizing the highly variable frontal sinus morpholog, the other paranasal sinuses and the mastoid air cells are neglected.[1-4] The maxillary sinuses are of notable importance due to their large size and very low rate of agenesis.[5] Additionally, capturing partial or whole maxillary sinus structures on routine dental radiographs greatly increases the potential applicability of maxillary sinus pattern-based identification. Likewise, mastoid air cells have similar potential, as they are frequently captured on cervical spine radiographs and Computed Tomography (CT) scans.[6] This presentation is one of the first to examine the usability of maxillary sinuses and mastoid air cells as a possible means of personal identification.

Abstract Text: One of the notable methods for personal identification in forensic anthropology is the comparison of antemortem and postmortem radiographs of the frontal sinus. The frontal sinus has been heavily researched and is recognized as showing individual variation in its morphology, ranging across many observable variables.[1-4,7] While frontal sinus pattern comparison is shown to be a reliable method, research utilizing other sinus spaces for personal identification has been overshadowed. The maxillary sinuses and Mastoid Air Cells (MACs) represent two under-utilized structures that have potential to vary in ways comparable to the frontal sinuses.[6,8-11] This study will assess maxillary sinuses and MACs for this purpose, focusing on aspects of size, with Surface Area (SA) and Volume (V) as metric variables.

Twenty-eight CT-scans from 15 males and 13 females were obtained from the New Mexico Decedent Image Database (NMDID).[12] Selection criteria included individuals 35-60 years of age, reported as "White" race, with no reported facial trauma or reconstructive surgery. CT scans of the craniofacial region were visualized using the 3D Slicer Image Computing Platform (http://www.slicer.org/) and sinus structures were isolated; the maxillary sinuses and MACs were captured bilaterally per individual.[13] Creation of segments was accomplished using various tools within the software to ensure accurate and complete capture of the structures. For the maxillary sinuses, all volume within the skeletal outline of each maxilla, whether hollow or filled, was captured; for the MACs, the region of each temporal encompassing the mastoid process and EAM was captured to ensure complete capture of the air cells.

Surface area (cm^2) and closed-shape volume (cm^3) were extracted from the segments and calculated using the "Segment Statistics, Quantification" tool in 3D Slicer. Data were then uploaded to R where tests of normalcy were conducted prior to conducting descriptive statistics. Statistically significant differences between sides were examined using Welch two sample T-tests and between sexes for each anatomical area using one-way Analysis of Variance (ANOVA). Based on the results of the one-way ANOVA, linear discriminant function analysis was also conducted.

The resulting range for surface area of the maxillary sinuses was between 19.7-55.5cm^2 and the volume ranged from 6.4-24.7cm^3. Ranges for the MACS were between 8.2-22.9cm^2 and 10.3-28.1cm^3, respectively. When examining the metric variables in relation to sex using one-way ANOVA, V was found to be significantly different in three variables: RMax (p=0.0293), LMAC (p=0.0327), and RMAC (p=0.0201), while one SA variable, (LMAC, p=0.0534), approached significance. These differences allowed for 85% correct sex classification using linear discriminant function analysis. No bilateral statistically significant differences within individuals were observed.

The results of this preliminary investigation found significant differences in volume in three of the four areas of study, especially as related to sex. This indicates the amount and distribution of space these regions occupy may be useful in developing personal identification methodologies. Although study limitations, such as sample size, should not be discounted, these results indicate that shape components may contribute further to sinus pattern variance and warrants additional research.

A13 Embedded in the Bones: An Investigation of Marginalization Through the Structural Vulnerability Profile

Navit S. Nachmias, BA, Texas State University, Crystal, MN; Kate Spradley, PhD, Forensic Anthropology Center at Texas State University, San Marcos, TX; Elaine Y. Chu, PhD, Texas State University, San Marcos, TX; Michelle D. Hamilton, PhD, Texas State University, San Marcos, TX*

Learning Objectives: After this presentation, attendees will understand the impact of marginalization and structural vulnerability on the human skeleton. This presentation will highlight the differences between what people have documented as marginalization and what information forensic anthropologists can glean from the skeleton. Attendees will also learn about the developing concept of a Structural Vulnerability Profile (SVP) and the validity of the biomarkers presented in a biocultural profile of that nature.

Impact Statement: This presentation will impact the forensic science community by providing information on how the human skeleton is affected by marginalization and how it impacts identifications. This presentation will also address the reliability of implementing the SVP in forensic investigations of skeletal remains.

Abstract Text: Recently, forensic anthropologists have advocated for the inclusion of structural vulnerability assessments in skeletal analysis. Given forensic anthropologists' unique osteological expertise, the goal of these assessments is to aid identifications and document and report potential patterns of inequality. To address the impact of marginalization in the skeleton, anthropologists have developed an SVP based on the principle that stress is embodied through specific biomarkers that may represent marginalization and limited resources to receive care.[1-3] These biomarkers include dental disease, enamel defects, porotic lesions, and the early development of age-related osteological conditions.[1,2] However, the SVP has been proposed based on the assumption that these biomarkers are related to marginalization and vulnerability.[4] While there are clear identifiers of marginalization in life (e.g., restricted access to employment, education, and housing, resulting in poverty and homelessness and evidence of inequality in the deceased (e.g., the disproportionate number of marginalized individual in forensic cases), there is currently no evidence that specific biomarkers have a strong association with particular experiences of marginalization.[2,5] Before anthropologists can implement the SVP to infer marginalization and vulnerability, a comprehensive test of the proposed biomarkers and their relationship to sex, race, ethnicity, and socioeconomic status, among other characteristics, must be performed on a well-documented skeletal collection. This project aims to investigate the relationship between proposed SVP biomarkers and demographics such as sex, race, ethnicity, socioeconomic status, and level of education to ascertain whether the biomarkers are indicative of marginalization.

Seven SVP biomarkers (abscesses, caries, antemortem tooth loss, Linear Enamel Hypoplasia (LEH), Cribra Orbitalia (CO), Porotic Hyperastosis (PO), and osteoarthritis) were collected from 100 decedents from the Texas State Donated Skeletal Collection at the Forensic Anthropology Center at Texas State. Individuals were grouped by adult socioeconomic status (i.e., low, middle, and upper-middle/upper). Within those groups, the individuals' sex, race, ethnicity, highest level of education, and childhood socioeconomic status were provided. The presence and absence of the biomarkers were compared within each demographic group using Multiple Correspondence Analysis (MCA), supplemented by Chi-Square and Fisher's Exact Tests, to assess the relationship between proposed biomarkers and demographics thought to be associated with marginalization. Results of MCA show associations between PO and sex and race, individually, LEH and ethnicity and education, individually, and caries and childhood socioeconomic status. These results are further supported by Chi Square and Fisher's Exact Tests. The results from the Chi-Square for sex and PO were significant ($p=0.01$) with an X-squared value of 6.5. The Fisher's Exact Test comparing race and PO ($p=0.02$), ethnicity and LEH ($p=0.017$), education and LEH ($p=0.03$), and childhood socioeconomic status and caries ($p=0.025$) were all significant at an alpha level of 0.05. While these results indicate there are relationships between some demographics and SVP biomarkers, overall, the Chi Square and Fisher's Exact Tests show few associations between the recorded demographics and SVP biomarkers. Therefore, forensic anthropologists should be apprehensive in their use of biomarkers to denote vulnerability and marginalization, particularly in the context of a profile such as the SVP.

A14 Is Sternotomy Wire Morphological Variation Sufficient to Support a Scientific Identification by Comparative Medical Radiography?

Christine M. Pink, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Jered B. Cornelison, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; B E. Charles, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

Learning Objectives: After attending this presentation, attendees will appreciate the morphological variation of sternotomy wires as viewed radiographically, and their utility for scientific identification using Comparative Medical Radiography (CMR).

Impact Statement: The results of this study quantify the variation of sternotomy wires outline shapes generated by Elliptical Fourier analysis. An analysis of Euclidean distances between all pairs of wires compared to antemortem-postmortem radiographs of the same wire indicate that sternotomy wire morphology is sufficiently individualizing to justify a personal identification via CMR.

Abstract Text: Forensic anthropologists are qualified to and often relied upon to perform personal identifications of unknown decedents using CMR methods. The essential question that must be asked when using the CMR method is, "Are the congruent features identified as the basis of the 'match' actually morphologically variable enough to be individuating?" With respect to surgical materials placed in the body, the presence of the object(s) is not enough to substantiate a positive identification (e.g., presence of a femoral stem implant for a hip arthroplasty). However, some surgical materials are quite variable. This study examined the variation in sternotomy wire outlines to evaluate whether they are individuating.

A sample of 20 decedents that received a postmortem exam between 2018 and 2025 and had sternotomy wires were included in this study. The most superior wire was isolated in a cropped image, converted to grayscale, and Elliptical Fourier coefficients were generated from nine harmonics for each with the DiaOutline101 application.[1] The coefficients were analyzed in R using the Momocs package.[2,3] Each outline was interpolated to 100 points used to calculate Euclidean distances between each pair of wires (n=190 comparisons) and between antemortem and postmortem outlines of the same wire (n=20 comparisons). The distance was calculated as the average distance between each pair of 100 points. When antemortem imaging was not available (n=6) the postmortem radiograph was retraced and substituted as the antemortem image. This study's methodology follows Christensen's study of frontal sinus shape variation.[4]

A Wilcoxon Rank Sum test resulted in a significant ($W=321$, $p< 0.0001$) difference in the mean Euclidean distance between pairwise comparisons of different wires (56.44) and antemortem-postmortem comparisons of the same wire (17.43). A Brown-Forsythe test of equality of variances resulted in a significant ($F=99.5$, $p< 0001$) difference when comparing the two distance distributions. Sternotomy wire configuration generally falls into two classes: single loop and X-shaped. The same tests were applied to the data subset by class. Loop-shaped wires (n=15) exhibited significance for both the difference in means ($W=201$, $p=0.000003$) and variance ($F=47.6$, $p< 0.0001$). Cross-shaped wire (n=5) comparisons were significant for both the difference in means ($W=0$, $p=0.0009$) and variance ($F=70.0$, $p=0.000006$).

These preliminary results indicate that the morphology of one sternotomy wire is likely individuating enough to support a scientific identification by CMR. Considering most individuals have several wires placed, the likelihood of a false positive "match" is low. Further analysis is necessary; however, these results are promising for the eventual validation of sternotomy wire morphology for personal identification via CMR.

A15 A New Methodology of Scoring DISH Severity: A Composite Scoring System

Lauren Nichols, MA, University of South Florida/ IFAAS, Temple Terrace, FL; Erin H. Kimmerle, PhD, IFAAS, USF, Tampa, FL*

Learning Objectives: After reading this poster, attendees will understand a new methodology of scoring the severity of Diffuse Idiopathic Skeletal Hyperostosis (DISH) spinal manifestations. DISH has been classified as present and absent and then later as late-stage and early-stage, but no standardized quantitative methodology exists in the published literature. The application of this method allows for better insights into the associative relationships of DISH and other ill-heath covariates and possible overall health of an individual with DISH.

Impact Statement: The application of the methodology allows for standardization of reporting DISH severity across research fields and further quantitative analysis into the condition. In the application of unidentified persons, the severity of DISH can allow interpretations into the possible health of the individual and the association of other ill-health covariates to assist with identification.

Abstract Text: DISH is a common spinal condition seen in modern and archaeological populations. The manifestations of DISH include the ossification of the right anterolateral ligament, leading to possible fusion of vertebrae. DISH manifestations have been classified as late stage and early stage.[1-3] Despite these classifications, individual cases within each stage can vary, thus making comparisons difficult. In addition, associative relationships with DISH and other ill-health covariates have been researched using the presence and severity of DISH.[1,2] The severity of DISH in these cases follow the same classification system that allows for greater variety in each stage.

This project focuses on the creation and utilization of a new quantitative severity scale based on the DISH spinal manifestations of individuals. The scale contains three subcategories that comprise the composite severity score: flow, bridging, and fusion. The flow and bridging scorings are adapted from Computed Tomography (CT) methodologies in medical research.[3,4] The severity score was then analyzed in comparison to health covariates of individuals in the University of South Florida's (USF) Donated Skeletal Collection. Within the total of 108 individuals in the USF Donated Skeletal Collection, 61 individuals were diagnosed with DISH by using the strictest criteria.[5] Each of these individuals have documented life history information and documentation. Analysis was completed through a combination skeletal analysis and archival documents to determine the severity of DISH and possible relationships. The presence of DISH was not influenced by any demographic characteristics or recorded ill-health covariates. DISH severity was influenced by sex toward males ($t = 4.017$; $df = 60$; $p < 0.001$; $d = 0.819$), increased weight (R = 0.431; $R^2 = 0.186$; $p < 0.001$; y=0.006x-0.046), and the absence of osteoporosis (t=1.935; df=60; p=0.029; d=0.79254).

Through the application of the severity scoring, comparisons between DISH cases can be more extensive. Further analysis of associative relationships between DISH severity and other health covariates can be achieved. Through the standardization of DISH severity scoring, the severity of DISH can be compared across projects and fields.

A16 The Application of Digital Quantitative Analysis From 3D Scans of Entheses for the Possible Use in Age Estimation

Gillian Stewart, BA, Louisiana State University, Baton Rouge, LA*

Learning Objectives: After attending this presentation, attendees will understand how 3D technology can be used to quantify entheses (muscle attachment sites on bones) for the potential use in developing a method for age estimation.

Impact Statement: This presentation will impact the forensic science community by demonstrating how entheses can be digitally quantified for the potential use in estimating skeletal age with the use of 3D scanning technology.

Abstract Text: Bone's functional adaptation to mechanical loading means that bone will adapt to forces to distribute the strain across a larger surface area.[1] Entheseal changes have been examined by anthropologists to infer occupation and repeated muscle movements, and their robusticity has been correlated with advancing age.[2,3] Analyses of entheseal changes use various scoring systems, usually based on an ordinal scale, to determine the degree of proliferative and erosive bone changes.[4] These methods rely on visual assessment that can be subjective to apply consistently.[5]

This project explores 3D technology for capturing entheses as digital data and quantifying their variation. Such digital quantitative analyses may provide an objective evaluation of entheseal changes that potentially could be applied to age estimation. Human skeletal remains from the New Orleans' Charity Hospital Site (16OR108) were examined in this study.

Four entheses were analyzed: the radial tuberosity (radius), deltoid tuberosity (humerus), gluteal tuberosity (femur), and tibial tuberosity (tibia). Entheses from five of each skeletal elements (MNI = 20) were scanned using an Artec Space Spider and digital data were processed to create 3D models in *Artec Studios v.18 Professional.* Tools available in the software program were used to take or calculate measurements of each enthesis that represented the length, width, height (i.e., the distance between the deepest and highest points, as represented by erosive and proliferative changes, respectively), and total Surface Area (SA). Each enthesis was also analyzed using a visual scoring method. Metric data were then compared to visual scores to check for congruency.

Results show that entheses can be rendered as digital models. Length, width, and SA measurements were produced, but height could not be obtained using the *Artec Studios* software. Also, no apparent pattern could be discerned between proliferative and erosive visual scores and the length, width, and SA measurements for any of the entheses or skeletal elements examined in this study.

This study demonstrates that 3D scans can show entheses clearly, even on remains with various degrees of preservation. Although some metrics were obtained, height was not. This axis most closely approximates what visual scores are based upon and, therefore, is crucial for quantifying entheseal robusticity. *Artec Studios* software was used in this study because of its convenience and availability; however, future research should examine other software programs, including Geographic Information Systems (GIS), to procure the height measurement.

Other important considerations for digital skeletal analysis are the amount of time it takes to become proficient with scanning technology and software and the large amount of processing power and storage needed to process and store the data. Also, smaller (i.e., the radius) and fragmented elements were harder for the technology to digitize. In conclusion, scanning technology can capture entheseal variation, but software that measures entheseal height (a proxy for robusticity) should be found and evaluated before it can be examined for use in quantitative age estimation.

A17 3D-CT-Based Estimation of Facial Soft Tissue Thickness in the Punjabi Population for Craniofacial Reconstruction

Akhilesh Pathak, APM, All India Institute of Medical Sciences, Bathinda, Punjab India, Bathinda Punjab, Punjab, India; Chandrakala Gadige, APM, All India Institute of Medical Sciences, Bathinda, Punjab India, Bathinda Punjab, Punjab, India*

Learning Objectives: Attendees of this presentation will gain a deep understanding of the challenges and advancements in identifying unknown skeletonized remains in forensic investigations. They will learn about the critical role of forensic experts and the use of techniques such as anthropological assessments, DNA analysis, and craniofacial reconstruction. The presentation will highlight advanced non-invasive tools like 3D-Computed Tomography (CT) imaging for recreating facial features from skeletal remains. Participants will explore the necessity of precise facial reconstruction methods and the importance of regional databases tailored to India's diverse anthropological characteristics. They will understand that Facial Soft Tissue Thickness (FSTT) data varies significantly across different regions of India due to ethnic differences and cannot be uniformly applied. The presentation will emphasize the need for an FSTT database specific to the Punjabi population, addressing how general data can lead to inaccuracies in forensic reconstructions. By the end of the session, participants will have a deeper insight into the importance of region-specific FSTT data for improving the precision and reliability of forensic identifications, thereby enhancing the effectiveness of medicolegal investigations.

Impact Statement: This presentation will address key challenges and advancements in identifying skeletonized remains, with a focus on diverse populations like India. Attendees will learn how integrating advanced techniques such as 3D-CT imaging with traditional methods enhances forensic identifications. The session will demonstrate the superiority of non-invasive imaging techniques like 3D-CT scans over traditional methods, showcasing their precise measurements crucial for accurate craniofacial reconstructions and modern forensic practices. A focus on creating an FSTT database for the Punjabi population will serve as a model for localized data in forensic applications. This will encourage the development of similar databases for other ethnically diverse regions, advancing forensic practices nationwide. The presentation will also serve as an educational resource for forensic science students and professionals, offering updated knowledge and best practices for handling skeletonized remains. Overall, this presentation will equip forensic professionals with advanced methods and insights, leading to more accurate identifications and better-informed decisions in legal and investigative contexts. This presentation will profoundly impact the forensic science community by addressing the critical challenges and advancements in identifying skeletonized remains, particularly in the context of diverse populations like India. Attendees will gain insights into the integration of advanced techniques such as 3D-CT imaging with traditional methods, enhancing the accuracy and efficiency of forensic identifications. The discussion on the use of non-invasive, advanced imaging techniques like 3D-CT scans will demonstrate their superiority over traditional methods. These technologies offer precise and detailed measurements that are essential for accurate computerized craniofacial reconstructions, paving the way for more modern forensic practices. The study's focus on creating an FSTT database for the Punjabi population will serve as a model for other regions, highlighting the need for localized data in forensic applications. This will encourage further research and the development of similar databases for other ethnically diverse regions, improving forensic practices nationwide.

Abstract Text: Identification of an unknown dead body is crucial in any medicolegal investigation. We frequently receive skeletonized remains for forensic autopsy, and identifying these remains presents a significant challenge. Forensic experts employ a combination of anthropological assessments, DNA analysis, and craniofacial reconstruction techniques to aid in identification. Traditional anthropological assessments estimate age, sex, and ethnicity from skeletonized remains. In cases without soft tissue, advanced tools like 3D-CT imaging can recreate facial features for comparison with photographs of missing persons.

DNA sampling is considered the primary means of definitive identification but is challenging in developing countries due to the lack of reference samples. In such cases, craniofacial reconstruction can help by creating a facial outline from the skull, which can then be used to reach out to relatives for DNA cross-matching. Advanced non-invasive techniques for facial reconstruction, such as X-rays, ultrasound, CT scans, and Magnetic Resonance Imaging (MRI), have surpassed traditional invasive methods.

There is a growing necessity for precise facial reconstruction methods with proper regional databases. India's diverse anthropological characteristics, influenced by genetic backgrounds and environmental factors, vary significantly across regions. Therefore, FSTT data from one region cannot be uniformly applied across different zones. For example, North Indians, South Indians, Gujaratis, Punjabis, and people from the Northeast exhibit diverse facial structures and tissue thicknesses. Hence, region-specific FSTT databases are essential for accurate and reliable forensic facial reconstructions across India. Currently, no FSTT database exists for the Punjabi population, presenting a challenge in creating accurate facial reconstructions. This lack of data can lead to inaccuracies, as the measurements may not reflect the true anatomical characteristics of Punjabis.

Establishing a comprehensive FSTT database for the Punjabi population is crucial for improving the precision and reliability of forensic facial reconstructions, thereby enhancing the effectiveness of identification processes in medicolegal investigations. In this study, we measured the FSTT of various landmarks in the Punjabi population using 3D-CT imaging to create a comprehensive database for facial reconstruction. This technique is less time-consuming and non-invasive, providing precise measurements necessary for accurate computerized craniofacial reconstruction. By focusing on the Punjabi population, this study ensures that reconstructions are tailored to their unique anatomical characteristics, significantly enhancing the reliability and accuracy of forensic identifications and contributing to more effective medicolegal investigations in the region.

A18 A Disabled Combat Soldier: Multiple Skeletal Anomalies With Klippel-Feil Syndrome

Hyejin Lee, PhD, MAKRI, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Changwon Lee, MA, MAKRI, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Learning Objectives: This study examines skeletal anomalies in the spine of a Korean War casualty, focusing on a rare congenital fusion of cervical vertebrae (C1 to C3). After attending this presentation, attendees will gain a better understanding of this uncommon condition and its possible impact on the soldier's functional abilities during life.

Impact Statement: Complete fusion of the C1 and C2 Vertebrae, including the odontoid process of C2 fused to the articular surface of C1, is known to be extremely rare even in clinical context. To the best of our knowledge, no such case has been reported in anthropological studies of human skeletal remains. This case may therefore provide meaningful insight for future research on congenital cervical anomalies.

Abstract Text: The Ministry of National Defense Agency KIA Recovey & Identification (MAKRI) has conducted systemic excavations for throughout South Korea, including the Demilitarized Zone (DMZ), with the aim of restoring unaccounted service members from the Korean War (1950–1953). The human remains of a soldier recovered in 2020 revealed skeletal anomaly diagnostic of Klippel-Feil Syndrome (KFS). KFS is thought to result from a failure of normal cervical vertebral segmentation during embryoninc development [1] and is known to be associated with various congenital malformations.[1-3] In this case, the vertebral bodies from C1 to C3 were fused into a block, with the odontoid process of C2 fully fused to the right superior articular facet of C1. Cervical vertebral fusion is a common feature of KFS, but involvement of C1 and C2 is rare.[4] Even rarer is fusion of non-separated odontoid process of the atlas, which, to the best our knowledge, has not been previously reported in the anthropological literature.[5,6] Fusion of the C1 and C2 vertebrae often leads to reduced neck mobility and limited head rotation, which can result in a noticeable tilt of the neck to one side.[7] Therefore, it can be inferred that this young combatant with a rare condition may have faced distinctive physical challenges in fierce battle situations.

A19 From Flesh to Formula: Devising a Modular Coefficient-Based System for Population-Specific Facial Soft Tissue Thickness Estimation in Forensic Facial Approximation

Shubham Thakur, MSc, Panjab University Chandigarh, Chandigarh, India; Jagmahender Singh Singh Sehrawat, PhD, Panjab University Chandigarh, Chandigarh, India*

Learning Objectives: After attending this presentation, attendees will be informed about the limitations of pooled Facial Soft Tissue Thickness (FSTT) datasets in accounting for individual biological variations and the significance of a modular coefficient-based model in estimating FSTT, which considers modifiers such as age, sex, Body Mass Index (BMI), ethnicity, craniofacial growth patterns, and the imaging modalities employed.

Impact Statement: This presentation will impact the forensic community by sensitizing the attendees about the potential benefits of using integrated modular, biological, and imaging-based coefficients for developing craniofacial identification models to be used in Disaster Victim Identification (DVI) and humanitarian contexts.

Introduction: The human face serves as a canvas for exploring personality and perception, encapsulating the essence of individuality and human expression. Beyond its aesthetic appeal, the human face plays a significant role in forensic anthropology, where its analysis is often essential for forensic identification in humanitarian contexts. FSTT is a key craniofacial component that provides vital information for generating accurate and reliable facial approximations.[1-3] It is important to note that facial soft tissue thickness is not a static characteristic; rather, it is influenced by various intrinsic and extrinsic factors.[4] Traditional pooled datasets (T-tables) frequently fail to account for this variability, which limits their applicability to the broader population.[5] Consequently, the present study seeks to address this issue by developing a modular coefficient-based model for customized inputs in facial approximations.

Methodology: The present study proposes a modular coefficient-based model aimed at dynamically estimating FSTT values. This is achieved by adjusting the estimates to population-specific base values, which are derived from coefficients calculated through meta-analysis. The model incorporates data from over 40 peer-reviewed studies and utilizes various radiological modalities, including cephalograms, ultrasound, MRI, CT, and CBCT scans. To facilitate this process, FSTT was calculated for 20 midline and bilateral craniofacial landmarks. The resulting equation encapsulates the core computational logic of the model:

Estimated FSTTi = Bi * Csex * Cage * CBMI * Cethnicity * Cgrowth * Cmodality

Where Bi represents the FSTT estimate at particular landmark i, and Cx represents the coefficient of modifiers x, derived from the effect size across variables.

Results and Conclusion: The findings revealed that the modular coefficient-based method displayed a deviation of less than 7% from the observed population datasets correlated with age, sex, and BMI. Furthermore, the landmarks located in the lower third of the face demonstrated the highest coefficient of sensitivity, especially concerning BMI and growth patterns as confounding variables. Consequently, this method offers a scalable alternative to pooled mean-based datasets by integrating inter-individual variability that is often overlooked in traditional reference datasets. The detailed results will be presented in textual, tabular, and graphical/diagrammatic form.

A20 The Morphological Variation of the Crista Galli in a Contemporary United States Population

Chastidy A. Gilbert, BA, University of Indianapolis, Rochester, MN; Stephen P. Nawrocki, PhD, University of Indianapolis, Indianapolis, IN; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN*

Learning Objectives: The goal of this presentation is to inform attendees about normal biological variation in the crista galli and the relationship of its morphometrics to demographic variables, including biological sex, age at death, and head size.

Impact Statement: This presentation will impact the forensic science and biological anthropology communities by documenting the normal biological variation of the crista galli in a contemporary United States sample. Understanding human variation is a fundamental first step before traits can be used in a predictive manner.

Abstract Text: Numerous methods have been developed to estimate aspects of the biological profile, yet many rely on morphological traits that lack adequate documentation of their normal variation. One such understudied trait is the crista galli, a midline endocranial projection of the ethmoid bone. Several studies propose using this structure for sex estimation, but the results are inconsistent across the literature. Some studies report strong correlations between crista galli dimensions and sex, while others find no significant associations. Many also fail to account for confounding factors like head size and age or are based on populations not representative of United States forensic cases.

This study aims to document and analyze the normal variation of the crista galli and assess whether its dimensions relate significantly to biological factors such as sex, age, and maximum cranial length in a contemporary United States population, using Postmortem Computed Tomography (PMCT) imaging. Data were collected from the New Mexico Decedent Image Database (NMDID), with a final sample of 272 individuals (159 males, 113 females).[1] Age at death (in years) was limited to individuals aged 20 to 80. Race and ethnicity were limited to "White" and "Non-Hispanic, Latino, Middle Eastern" due to underrepresentation of other groups and to reduce confounding in statistical analyses. Exclusion criteria included facial trauma, missing imaging data, or any conditions affecting normal variation of the crista galli. Blind measurements of crista galli length, width, and height followed Hajiioannou et al.; maximum cranial length (GOL) was measured per *Standards for Data Collection from Human Skeletal Remains*.[2,3] Presence or absence of crista galli pneumatization was also recorded. All variables were kept continuous to preserve statistical sensitivity.

Analysis of Covariance (ANCOVA) models tested whether sex, age, or GOL significantly predict crista galli dimensions. For length, no predictors were significant, and the model explained only 0.8% of total variance ($R2 = 0.008$). The model for width was significant ($p = 0.00029$), with GOL and age being significant predictors ($p = 0.00134$ and 0.044), explaining 6.8% of variance. Height was significantly predicted by both GOL ($p = 0.000248$) and sex ($p = 0.00286$), with males having, on average, 1.37 mm shorter crista galli heights when controlling for age and GOL. This model explained 7.6% of the variance with a p value < 0.0001. Further ANCOVA models determined there is a statistically significant relationship between age and the height of the crista galli in females, suggesting a relationship with hyperostosis cranii. Binary logistic regression found no significant relationships between pneumatization and sex ($p = 0.4029$), age ($p = 0.388$), or GOL ($p = 0.249$), although pneumatization was rare (~7% frequency).

This study addresses previous limitations by using a demographically appropriate United States sample and more robust statistics. Results show that while some crista galli dimensions moderately covary with head size, sex, and age, the low explained variance suggests that other unrecorded factors contribute more to its variation. These findings reinforce inconsistencies in previous literature and suggest that the crista galli may not be sufficiently patterned to be a reliable tool for forensic identification.

A21 Human Body Donation and Donated Skeletal Collection Data Management: The Advantages of Building an Internal Database for Education and Research

Skyler M. Yakes, MA, LSU FACES Laboratory, Baton Rouge, LA*

Learning Objectives: From this presentation, attendees will learn advantages for developing an internal database to manage human body donation programs and skeletal research collection. The presentation includes examples of interface design, data entry, and search results from querying that highlight the advantages of building a database that can be adapted to suit the unique needs of human skeletal collections.

Impact Statement: With the growth of human body donation programs and skeletal research collections across the country, this presentation proposes a model for creating a functional internal database for effective data management of human skeletal remains.

Abstract Text: Modern skeletal research collections, like the Louisiana State University Forensic Anthropology and Computer Enhancement Services (LSU FACES) Laboratory's Donated Skeletal Collection (DSC), rely on human body donation programs to facilitate the donation of a person's body after death for indefinite curation.[1] Over the past several years, LSU's DSC has grown considerably due to living (or self-willed) and next of kin donations. The growth has initiated efforts to better manage data for donation processes, curation, education, and research using human remains.

The database was developed for the LSU FACES Laboratory to better store information relating to the lab's processes as well as its digital and physical data relating to human remains. The database includes pages on the donation process, donor information, taphonomy, and skeletal analysis. Each page has fields for data entry and is linked to the assigned case number. The donation process has fields relating to type of donation (e.g., coroner, next of kin, or living donation), record of provenience, type of consent (e.g., verbal, coroner letter, donation consent form), and samples collected during arrival procedures (e.g., X-rays, hair sample, or nail sample). The donor information page includes reported demographics, medical history, habitual activities, and location(s) of residence. The fields distinguish between reported (i.e., coroner, next of kin, or self-reported) and estimated demographics. Taphonomy contains placement and retrieval information at the Forensic Taphonomy Education and Research Facility (FTERF), taphonomic assessments, scavenging, and entomology. The skeletal analysis page incorporates a bone inventory, dental chart, and trauma and pathology fields. The design mimics laboratory forms and data collection procedures to aid in transferring information to the database.

The database is a functional tool that stores and queries useful data for education and research. The benefit of creating an internal database is the ability to update and change data fields to best serve specific laboratory processes and data usage. The database is a living, workable integration into the lab that aids proper documentation and patterns of use for research and education. For example, lists of ideal specimens that can serve as exemplars for trauma, pathology, or characteristic bioprofile features can easily be generated for use in classrooms. Future additions to the database are planned and include pages regarding research and 3D scanning. These data can link research projects and educational use with specific donations, thus enabling impact reports to be generated for the families and loved ones of the donors.

The choice to donate is a special interaction between forensic anthropologists and the communities they serve. As the number of donors for long-term curated skeletal collections increases, the responsibility to ensure proper care for such donations extends to include the data they provide and the ways in which such data are stored and utilized. The database will be a tool that continues to adapt to the specific needs of the laboratory and the care of donated skeletal remains.

A22 A Retrospective of Forensic Anthropology Casework at Two Rural University Labs, 2018–2025: Trends, Challenges, and Implications

Samantha H. Blatt, PhD, Idaho State University, Pocatello, ID; Amy Michael, PhD, University of New Hampshire, Rochester, NH*

Learning Objectives: Attendees will learn about the nature and composition of casework by practicing forensic anthropologists at two rural universities in Idaho and New Hampshire from 2018–2025. A retrospective, comparative account of casework completed at these institutions will introduce trends in case types and operationalization of rural, resource-limited practitioners.

Impact Statement: This presentation will benefit the forensic sciences community by quantifying and contextualizing forensic anthropology casework in rural, university settings. Review of a forensic anthropologist's casework is infrequently published, and the current body of such work primarily focuses on urban jurisdictions, practitioners operating within large medical examiner's offices, multiple decades, and specific case types or cases of public interest.[1-6] This presentation demonstrates how reviewing casework trends from rural jurisdictions is fundamental to supporting practitioners with developing jurisdiction- and laboratory-specific strategies that align with available resources.

Abstract Text: This study presents a comparative analysis of forensic anthropology casework (2018–2025) conducted at two rural, mid-sized universities in Idaho and New Hampshire. It examines the volume, nature, and outcomes of forensic cases, and how geographic, institutional, and community-specific factors influence casework in rural contexts. Both states are defined by dispersed rural populations, limited forensic infrastructure, and distinct environmental conditions that affect death investigations. This research evaluates how forensic anthropologists in these settings navigate logistical, institutional, and sociopolitical challenges and how such factors shape trends in casework.

The study addresses a gap in current literature, which focuses on urban centers, long-standing medical examiner systems, or well-resourced academic institutions.[1-6] Rural forensic anthropology is often overlooked, despite its critical role in supporting local law enforcement, handling complex regional death investigations, and representing under-identified or under-served decedents.[4] By highlighting constraints and innovations emerging in rural contexts, this project demonstrates need for equitable distribution of forensic resources, standardized protocols, and policy-level support for rural practitioners.

Data were collected from institutional and practitioner records to assess case types (e.g., skeletal identification, trauma analysis, search and recovery), caseload volume, time to resolution, and collaboration with local authorities. The study also compared methodological approaches, reporting practices, and the use of emerging technologies.

Findings suggest rural institutions can serve as models for adaptive, community-integrated forensic practice. As the discipline of forensic anthropology continues to professionalize, understanding rural casework is essential to building a field that is both scientifically rigorous and socially responsive. This research offers a foundation for future efforts to document and improve forensic anthropology in underserved areas. In Idaho, casework often involves outdoor recoveries in rugged terrain—deserts, forests, mountains, and agricultural zones—with cases intersecting issues of land use, Tribal sovereignty, outdoor recreation, and unidentified remains possibly linked to migratory populations. Environmental exposure and scavenger activity frequently complicate recovery and analysis. In New Hampshire, cases typically involve individuals found in wooded or transitional semi-urban zones, often discovered during seasonal thaw. Cold climates affect decomposition in both states but create distinct region-specific challenges.

Despite these geographic and environmental differences, both institutions face similar systemic barriers: limited access to advanced forensic technologies (e.g., Computed Tomography [CT] scanning, isotopic labs), lack of full-time forensic anthropology positions, and inconsistent funding. Still, practitioners at both sites exhibit resilience and adaptability—developing strong interagency collaborations, using low-cost documentation tools, and involving students in casework to maintain scientific standards and meet community needs. One key finding is the modest but steady increase in case referrals at both institutions over the decade, likely tied to increased public awareness and growing reliance on academic forensic anthropologists in rural jurisdictions. This trend underscores the importance of building sustainable infrastructure and long-term capacity in these regions. By identifying both shared and regionally specific practices, this project contributes to a more inclusive understanding of forensic anthropology across diverse landscapes. It offers a framework for enhancing rural forensic services, advocating for institutional support, and ensuring all communities—regardless of size or location—receive scientifically sound, ethically grounded death investigation services.

A23 Standardizing Skeletal Sex: A Review of Terminology, Cited Methodology, and Bias-Mitigation in the Standards and Training Documents of United States Forensic Anthropology Institutions

Taylor M. Flaherty, PhD, University of Nevada, Las Vegas, Detroit, MI; Marion Davidson, MSc, University College London, Baltimore, MD; Allysha P. Winburn, PhD, University of West Florida, Pensacola, FL*

Learning Objectives: Forensic scientists attending this presentation will learn how American National Standards Institute (ANSI) National Accreditation Board (ANAB) -accredited forensic anthropology laboratories, documents published by the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) Forensic Anthropology Subcommittee, and additional procedural guidelines from United States forensic anthropology laboratories define and apply terminology, select methods, and implement bias-mitigation strategies when estimating skeletal sex. Attendees will better understand current levels of consistency between institutions and key areas of improvement for procedural reliability.

Impact Statement: Practitioners will understand details of published anthropological standards and the Standard Operative Procedures (SOPs) developed by leading laboratories estimation encouraging an evaluation of their own laboratory protocols related to skeletal sex estimation. Noting linguistic and procedural variability, this presentation will highlight the importance of consistent, bias-aware approaches in forensic analyses of skeletal sex. Ultimately, these findings will contribute to ongoing discussions of credibility and praxis in medicolegal investigations.

Abstract Text: As the field of forensic anthropology continues to strengthen and standardize approaches to casework, discussions of accreditation and synchronicity have emerged. From individual research teams to the ISO, forensic scientists have emphasized the need for consistency between practitioners.[1,2] Oft cited as one of the most critical components of the biological profile, skeletal sex estimates may simultaneously be impacted by various biological and environmental factors that complicate anthropological assessments. Over the past decade, forensic anthropologists have begun to interrogate linguistic and methodological preferences related to skeletal sex estimates and how well these represent natural variability in human sexual sex.[3] Research has also indicated that methods used to estimate skeletal sex may be susceptible to cognitive biases that jeopardize their reliability.[4,5] Inconsistencies and biases across institutions may compromise scientific rigor and legal admissibility. In response, forensic anthropology laboratories and the AAFS Standards Board have been working diligently to guide nuanced conversations related to skeletal sex, modifying standard operating procedures and resources with the emergence of continued research. This study seeks to evaluate how accredited forensic anthropology laboratories and affiliated institutions approach skeletal sex estimation and bias mitigation within their best practice guidelines.

This research presents a qualitative content analysis of SOPs and training materials from ANAB-accredited forensic anthropology laboratories as of 2024, NIST OSAC documents published through 2025, and additional procedural guidelines from United States forensic anthropology laboratories collected via public domain or personal communication. The primary aim was to assess the consistency of terminology, analytical approaches, and documented procedures for minimizing bias in skeletal sex estimation. Specific attention was given to how terms such as “sex,” “probable sex,” “dimorphism,” and “bias” were defined and operationalized; as well, procedures for proficiency testing, periodic review of standard operating procedures, and the integration of recent literature were recorded.

Each document was reviewed and deductively coded using a codebook developed by a team of forensic anthropologists with varying levels of casework and research experience. To support methodological rigor, the coding structure was, in part, modeled after studies examining standard operating procedures for friction ridge examination in forensic laboratories.[6] Patterns within the data were then analyzed to assess the degree of uniformity across institutions. Preliminary findings suggest considerable differences between institutions when outlining and discussing related to estimating and reporting skeletal sex. There was also a notable absence of cited literature for reference. Evident attempts are being made to mitigate overall case bias, however, most notably by setting a clear order of laboratory analyses, including skeletal assessments conducted before the review of contextual evidence.

Underscoring the ongoing need for standardized, evidence-based language and methodology related to skeletal sex, as well as bias-mitigation strategies, this study provides key insight for future casework and accreditation practices. High levels of consistency between forensic anthropology practitioners and institutions will not only offer cohesive recommendations for best practice, but will also ensure credibility, competency, and stakeholder trust.

A24 Methodology Trends in Forensic Anthropological Casework and the Implications for Current Practice

Jasper K. Shaw, MA, University of Central Florida, Barboursville, WV; Donovan M. Adams, PhD, University of Central Florida, Orlando, FL*

Learning Objectives: After this presentation, attendees will have a better understanding of trends in forensic anthropological methodology usage since the 1970s and how current trends may impact practice and teaching in the field of forensic anthropology.

Impact Statement: This presentation will impact the forensic science community by assessing how practices of estimating the biological profile may have shifted over time and how these compare to research trends. The implications of how casework and research methods differ may affect the education of future forensic anthropological practitioners, what type of methods may warrant further research given their usage, and what methods are most taught and practiced. The findings in this presentation will encourage practitioners to examine possible patterns in choosing methods to estimate the biological profile, as well as the applicability of certain methods based on a research or casework context.

Abstract Text: Research on forensic anthropological methods for estimating some aspects of the bioprofile appears to favor the production of metric methods (Ferrell et al.), although recent surveys have shown a preference among forensic anthropologists for using morphological methods in casework (Garvin and Passalacqua;
Klales).[1-3] These trends suggest that the discipline is quite different between casework and research environments and encourage further investigation into how the needs for method performance (e.g., accuracy and precision) may vary in each aspect of the field.

This research examines if previous findings regarding methodological preferences in casework, the use of morphological methods, is evident in submitted case reports as part of the Forensic Anthropology Database for Assessing Methods Accuracy (FADAMA).[4] A total of 641 cases dated between 1972 and 2022 were accessed through the FADAMA to examine which methods of estimating the bioprofile are most frequently used as well as how the usage of those methods has changed over time. Each case was examined for specified methods for each aspect of the bioprofile. Methods were categorized as either morphological- or metric-based to assess which type of method was preferred in casework. Descriptive statistics were run as well as Jonckheere-Terpstra tests to evaluate whether a given method displayed significant changes in usage over time. A Cochran-Armitage test was used to evaluate whether there were differences between morphological and metric method usage, for each aspect of the bioprofile.

There were 38 sex methods, 75 age methods, 28 population affinity methods, and 18 stature methods cited in total. None of the Jonckheere-Terpstra tests indicated significant increasing or decreasing trends over time ($p < 0.05$) for each individual method listed in the FADAMA. The Cochran-Armitage tests showed that sex estimation methods showed significant differences between morphological and metric method usage ($Z = -2.1082$; $p = 0.035$). Overall findings reflect a clear preference for morphological methods, which account for 75% of method usages across all combined date ranges (98% for age; 57% for population affinity; 80% for sex; 0% for stature). Specific methods that reflected preferential usage were Phenice (1969) (19% of 1116 total counted citations) and generalized morphology (19%) for sex, Brooks and Suchey (1990) (21% of 1869 total counted citations) for age, and FORDISC for population affinity (41% of 1000 total counted citations) and stature (80% of 413 total counted citations).

These findings primarily suggest that older methods may be more favored due to a variety of factors, including perceived accuracy, reliability, appropriateness for specific contexts, and exposure during training. There may be hesitance to implement newer methods in forensic casework because the older methods are highly trusted, widely taught, and consistent while newer methods have not necessarily undergone rigorous testing, been used as much due to their newness, or might not have been taught in a student's program. There is evidence that forensic anthropology practices are different in research compared to casework, given patterns in the literature, which could create gaps in knowledge of the bioprofile.

A25 The Value of Forensic Anthropological Postdoctoral Fellowship Training in a Medical Examiner Setting: A Four-Year Retrospective Reflection

Helen Litavec, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Devora Gleiber, PhD*, Erie County Medical Examiner's Office, Buffalo, NY Jason M. Wiersema, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Miriam E. Soto Martinez, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Julie M. Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: The goal of this presentation is to provide attendees with a retrospective reflection on the first permanent, county-funded, forensic anthropological postdoctoral training-only program in a Medical Examiner's or Coroner's (ME/C) office, now in its fourth year. Inaugurated in 2022, and presented in 2023, the benefits of this current fellowship program at the Harris County Institute of Forensic Sciences (HCIFS) are highlighted and potential areas for improvement are addressed.[1]

Impact Statement: This presentation will impact the forensic science community by discussing the skills and knowledge gained by participating in ME/C casework, often unavailable to students in academic institutions. This presentation describes the experiences of two recent fellows and underscores the need to increase the number of fellowship opportunities for early-career forensic anthropologists.

Abstract Text: Forensic anthropologists have recently begun to evaluate the lack of uniform education in the discipline—graduate students often receive focused training in some areas (e.g., biological profile) but less exposure to others (e.g., trauma), making it nearly impossible to become well-rounded practitioners by completion of their graduate school program(s).[1] Additionally, exposure to legal training and the courtroom is limited, insufficiently preparing early-career professionals for expert witness testimony.[2,3] The HCIFS's forensic anthropology postdoctoral fellowship was designed to address these issues.

After one year (or more) of immersive, hands-on experience under the guidance of three board-certified staff forensic anthropologists in an accredited forensic anthropology laboratory—operating in a high-volume ME office—the fellows reflected on the valuable acquisition of the following skills/knowledge: (1) extensive exposure to the diverse spectrum of osseous/cartilaginous trauma analyses; (2) recognition that pediatric injuries are not equivalent to those of adults; (3) learning how to effectively describe, interpret, and phrase relevant findings to competently author reports; (4) experiencing the necessary, yet uncomfortable, process of rigorous peer review; (5) working in consultation with forensic pathologists and learning how to suggest the most effective means for answering their questions; (6) training in utilizing postmortem imaging to identify trauma and unknown decedents; (7) preparation for expert witness testimony, observing the adversarial nature of courtroom proceedings, and participating in a mock trial; (8) immersion into the maintenance of accreditation; and (9) engaging in dynamic conversations regarding professionalism, challenges, and milestones within the field. The insights shared are invaluable to the professional development of burgeoning forensic anthropologists.

Of the approximately 400 analyses completed by the HCIFS anthropologists annually: 70% are adult and pediatric trauma; 20% are identification requests; and the remaining 10% include estimating the biological profile and the assessment of pathological conditions and non-human remains. This emphasis on osseous, cartilaginous, and pediatric trauma is generally in stark contrast to the focus on biological profile development in forensic anthropology education. The discrepancies between the types of casework potentially conducted in graduate school versus an ME/C office often leave deficits in the toolkits of early-career professionals. We argue that a PhD is not the termination of education, training, and growth; forensic anthropology competency requires the acquisition of additional knowledge and skill that are addressed by this fellowship.

The fellowship structure is designed to be adaptable and responsive to the American Board of Forensic Anthropology. In 2024, the fellowship transitioned from one year to two, permitting more exposure for the fellow and more caseload sharing for the staff. The training modules have been adapted based on lessons learned, and the training pace can be adjusted for each fellow. Areas for improvement included suggestions to renovate the goals of the program to address the new multi-level certification process and competencies necessary for the newly created analyst exam. This fellowship effectively addresses the gap between the educational and professional spheres, is actively evolving to address the changes within the field, and should be applied and modeled in other ME/C offices across the country.

A26 An Investigation Into Academic Inbreeding and Prestige Bias in Forensic Anthropology

Nicholas V. Passalacqua, PhD, The Ohio State University, Hilliard, OH; Natalie Clark, BA, Michigan State University, East Lansing, MI; Joseph T. Hefner, PhD, MSU, East Lansing, MI*

Learning Objectives: The goal of this presentation is to examine prestige bias and academic inbreeding within academic forensic anthropology programs in order to assess the academic health of the discipline.

Impact Statement: This presentation will impact the forensic community by demonstrating that prestige bias and academic inbreeding exist in forensic anthropology, and both may be negatively impacting the discipline.

Abstract Text: Academic inbreeding (universities hiring their own graduates) occurs in fewer than 20% of United States faculty appointments.[1] Scholars agree it is undesirable because it leads to "knowledge atrophy," as insular faculty stifle innovation.[2] By contrast, bringing in outsiders introduces fresh perspectives and external collaborations, renewing ideas and preventing stagnation.[2]

Academic inbreeding studies typically examine scholarly productivity using the *h*-index, which quantifies productivity and the impact of scholarly work, and is calculated as the *h* number of publications cited *h* times. Studies examining scholarly productivity and endogamy have demonstrated inbred faculty have inferior scholarly productivity compared to non-inbred faculty. Inanc and Tuncer found non-inbred faculty had 35% higher *h*-indices, compared to inbred faculty.[3] We, as well as other literature on this topic, acknowledge teaching and service are also crucial to faculty and university success; however, these areas are more difficult to assess.

Academic inbreeding often occurs in conjunction with prestige bias. Prestige bias is the concept that the reputation of an academic department or university, rather than merit, affects the academic labor market. There is broad consensus that the prestige of the department/institution where an individual received their doctoral degree is the most important factor affecting employment opportunities.

We investigated academic inbreeding and prestige bias in forensic anthropology education programs in the United States. We defined forensic anthropology education programs as programs employing two or more forensic anthropologists as faculty. Based on these criteria, we identified 14 programs consisting of 42 forensic anthropology faculties. Faculty in these programs were evaluated based on the program(s) from which they received their graduate degree(s). Faculty were considered inbred if they earned their master's or doctoral degrees from the institution where they were currently employed. The *h*-index of each faculty member was obtained using Google scholar, which captures a wider array of publication and citation information. For individuals without Google Scholar profiles, *h*-index was calculated from citation records obtained from Web of Science.

The presence of prestige bias within the sample was suggested as The University of Tennessee, Knoxville was overwhelmingly represented as the institution of doctoral degrees; 13 of the 42 faculty (31%). However, no significant differences in *h*-index were found for those faculty compared to other faculty in the sample, signifying there was no evidence for scholarly upturn via prestige. Academic inbreeding was also observed in the sample, with 13 faculty (31%) currently employed in the department where they earned one of their graduate degrees. Consistent with the literature, inbred faculty here were found to have lower median *h*-index values compared to their non-inbred counterparts.

We found evidence to suggest that academic inbreeding and prestige bias are present within forensic anthropology; with no evidence to support that individuals experiencing prestige bias were more productive than their more meritocratic counterparts, but that academic inbreeding did appear to negatively impact scholarly productivity. While this sample is limited and further research is needed, results suggest that programs should seek to hire faculty with diverse backgrounds and that the labor market may be overly limited.

A27 Intra-Observer Error in Osteometric Data

Maggie M. Klemm, MA, University of Nebraska-Lincoln, Lincoln, NE; Dakota L. Taylor, MA, University of Nebraska Lincoln, Lincoln, NE; William R. Belcher, APM, University of Nebraska, Lincoln, Lincoln, NE;*

Learning Objectives: After attending this presentation, participants will gain a clearer understanding of how intra-observer error and measurement replicability can affect the accuracy of osteological data and, consequently, the reliability of forensic anthropological estimates.

Impact Statement: This presentation aims to impact and advance the forensic science community by contributing to the improvement of standards and methods in osteometric data analysis. The findings will support ongoing efforts to standardize practices within forensic anthropology, ultimately enhancing the reliability and consistency of the discipline.

Abstract Text: In forensic anthropology, osteometric data is commonly used to estimate an individual's stature, age-at-death, and biological sex. However, despite its widespread application, limited research has assessed the intra-observer error rates associated with these measurements. Intra-observer error refers to variations in repeated measurements taken by the same individual, and such variability, along with factors like experience level and measurement replicability, can impact the reliability of forensic estimates.[1,2] This research is critical to advancing forensic science by highlighting the need to account for intra-observer error when collecting and interpreting osteometric data.

This study aims to determine the intra-observer error and reliability rates of repeated osteometric measurements, through standardized cranial and post-cranial measurements as established in the *Data Collection Procedures for Forensic Skeletal Material 2.0*.[3] Cranial and post-cranial osteometric data were collected from 14 different observers. Six high-quality skeletal casts were used for this study, and each observer selected two casts to take their measurements from. Approximately 38 cranial (including mandibular) and 57 post-cranial measurements were taken with reference to the Central Identification Laboratory (CIL) standard measurements.[4,5] Each observer took the measurements twice, totaling 76 measurements per cranium and 114 post-cranial measurements per post-cranial skeletal cast. The observers performed the measurements independently and with no outside assistance during an academic semester. Data were analyzed in RStudio by conducting One-way Analysis of Variance (ANOVA) to examine the intra-observer error rates. This was done through a comparison of the spread of the measurements taken by each observer. Presently, an acceptable error range is for osteometric measurements to be within a 2-millimeter range of the known and/or repeatable measurements.

The results of this research demonstrate significant intra-observer variability among the observers. Among the most reliable in this study were Observers One, Seven, and Eight, with 89.4%, 80%, and 86.8% of their total repeated osteometric measurements falling within the standard 2-millimeter error range, respectively. Observers Six, Eleven, and Nine had the least agreeability, with 56.5%, 51.3%, and 64% of their total repeated osteometric measurements falling within the acceptable error range, respectively. The post-cranial osteometric data yielded similar results to the cranial measurements; however, with less significant intra-observer variability. Observers One, Five, and Eight had the least intra-observer variability, with 97.3%, 94.6%, and 95.5% of their total repeated osteometric measurements falling within the acceptable error range, respectively. Observers Six, Seven, and Eleven had the least reliability, with 53.5%, 72.1%, and 71% of their total measurements within the acceptable error range, respectively. This research examines specific osteometric measurements that exhibit higher intra-observer error rates, with a focus on exploring how teaching and training practices can be improved in forensic anthropology to minimize these discrepancies. The findings highlight the importance of considering intra-observer reliability when collecting osteometric data, as measurement variability can significantly impact forensic anthropological estimates such as biological sex, age-at-death, and stature.

A28 Skeletal Trauma in Pediatric Homicides and Suspicious Deaths: A 6-Year Retrospective Review at the West Tennessee Regional Forensic Center

Mackenzie Strobel, BA, West Tennessee Regional Forensic Center, Memphis, TN; Diana Messer, PhD, West Tennessee Regional Forensic Center, Memphis, TN*

Learning Objectives: Attendees will gain insight into the prevalence, distribution, and characteristics of skeletal trauma in suspicious or homicidal deaths of children under four years old investigated at the West Tennessee Regional Forensic Center (WTRFC). Attendees will learn how skeletal injury patterns can inform recognition of inflicted trauma and mechanisms of injury in pediatric deaths. Attendees will also learn how forensic data, when paired with investigative and medical histories, can identify gaps in early intervention and inform prevention strategies.

Impact Statement: This presentation will impact the forensic science community by providing a region-specific analysis of skeletal trauma in pediatric deaths revealing injury trends and associated sociodemographic conditions. These findings can enhance forensic practitioners' abilities to recognize non-accidental trauma, refine postmortem investigative protocols, and have the potential to improve data-driven prevention measures.

Abstract Text: Homicide is a leading cause of death among United States children, with Tennessee's child fatality rate 22.6% above the national average.[1,2] Infants and children under age three experience the highest rate of physical abuse, with skeletal fractures highly concerning for non-accidental trauma.[3] The location and timing of these injuries can provide insight into mechanisms and injury patterns. To better understand characteristics and distributions of inflicted skeletal injury and associated risk factors in Western Tennessee, this study examines skeletal fractures in suspicious or homicidal deaths of children under the age of four.

A retrospective review was performed of pediatric decedents (≤ 3 years) with skeletal trauma investigated by the WTRFC between January 1, 2019, and December 31, 2024. Cases were included if manner of death was classified as homicide or deemed undetermined or pending with suspicion for non-natural cause. Exclusions included skeletal trauma from firearms, Cardiopulmonary Resuscitation (CPR), or accidental causes. All available postmortem documentation was reviewed, including investigative records, autopsy and anthropology reports, and medical histories.

Among 184, 30 children (23 males, 7 females) met inclusion criteria with manner of death classified as homicide (n=17), undetermined but suspicious for non-natural causes (n=9), or pending with concern for non-natural cause (n=4). Between 2019 to 2024, an average of 2.5 pediatric deaths fit these categories. Most children were under 12 months old (n=22), and 10 (33%) had known prior Child Protective Services (CPS) involvement. Blunt trauma was the leading cause of death (n=17), followed by asphyxia (n=5). Seasonal variation was observed, with the highest number of cases during winter (30%) and the fewest in spring (20%). Nearly 60% of cases occurred during fall and winter. Geographic clustering was noted in the urban core (43%) and suburban Memphis (40%), with 17% from rural areas.

On average, each child sustained approximately six skeletal injuries, with the thorax and head most commonly affected. Both ante- and perimortem trauma were present in more than half of cases. Five children had at least one metaphyseal fracture, most frequently involving the distal femur or distal humerus. Thoracic antemortem injuries were present in 50% of cases, averaging four rib fractures per child, primarily involving posterior ribs 1–7. Perimortem skeletal injuries were documented in 25 children, including long bone fractures (n=13) and cranial trauma (n=11).

Seasonal and geographic trends may reflect environmental, socioeconomic, or psychosocial stressors. Posterior rib fractures indicative of forceful chest compression, multiple healing fractures suggesting repeated trauma, and metaphyseal fractures likely from abnormal stress to a joint are consistent with repeated forceful handling (e.g., squeezing, pulling) as well as acute traumatic events (e.g., hitting).

Low rates of CPS involvement may suggest a need for earlier detection of abuse indicators, including during routine wellness visits. These results highlight the necessity of skeletal surveys, anthropological analysis, and autopsy once a fatality has occurred. Targeted prevention and child protection initiatives in densely populated urban and suburban areas during colder months could improve detection of non-accidental trauma and inform broader child protection strategies.

A29 Diagnosing Elder Abuse From Skeletal Trauma: A Bayesian Approach to Distinguish Abuse From Accidental Falls

Jacob A. Harris, PhD, Arizona State University, Phoenix, AZ; Laura C. Fulginiti, PhD, Clark County Office of the Coroner/Medical Examiner, Mesa, AZ; Katelyn L. Bolhofner, PhD, Arizona State University, Phoenix, AZ; Jane E. Buikstra, PhD, Arizona State University, Tempe, AZ*

Learning Objectives: After attending this presentation, attendees will be aware of a novel statistical method to accurately and objectively differentiate skeletal trauma from cases of elder abuse and accidental falls.

Impact Statement: This presentation will impact the forensic science community by demonstrating the enormous potential of probability approaches to diagnosing cases of elder abuse from skeletal trauma.

Abstract Text: By the year 2023, individuals 60+ will comprise 20% of the population of the United States, and it is estimated that 10% of adults aged 65+ will experience some form of abuse annually. In the United Kingdom, a recent study found that 22% of residents 65+ surveyed had personal experience of abuse or knew an older person who had been abused.

Physical abuse represents the most severe manifestation of this trend, yet it is difficult to prove. Skeletal expressions of abuse offer key indications of inflicted and untreated injuries but often are masked by assignation to accidental falls. In the current study, we address the research question: can skeletal trauma from accidental falls be systematically and accurately differentiated from abuse or neglect? The results of our 2018 pilot study identified differential patterns of skeletal trauma associated with abuse and accidental falls and in the current study, we tested the hypothesis that certain regions of the body (e.g., head and neck, upper appendicular, etc.) are differentially associated with either abuse or accidental falls by modeling our sample (n=394) of skeletal trauma of known origin within a non-hierarchical Bayesian framework. Our model, trained to differentiate between “Abuse” and “Accident” categories, performed with an average success rate of 70% (Posterior P(Abuse) = 0.82 Posterior P(Accident) = 0.65). The posterior results of our model further suggest, within our sample, skeletal trauma from abuse is more likely to occur in the upper appendicular and upper rib regions of the body, while skeletal trauma in the pelvis and trunk vertebrate regions is more likely among accidental fall cases.

A30 A Comparative Macroscopic Study of Bone Quality and Fracture Frequency in Individuals With and Without Arthroplast

Theresa De Cree, MS, Texas State University, San Marcos, TX; Danny J. Wescott, PhD, Texas State University, San Marcos, TX*

Learning Objectives: After attending this presentation, participants will understand the effects that arthroplasty has on the fragility of the human skeleton. Consequently, participants will see how those factors influence trauma analysis for elderly individuals.

Impact Statement: The result of this study will impact both forensic anthropology and the medical field as the understanding of arthroplasty on fracture rates can improve both analysis in death investigations as well as considerations for orthopedic practitioners for best practices in arthroplasty follow-up.

Abstract Text: As life expectancy increases, instances of diseases and conditions associated with older age rise concurrently.[1] Arthroplasty, or joint replacement surgery, can be used to treat arthritic joints that have degraded and cause pain. Occurrences of arthroplasty are on the rise; therefore, understanding its long-term effects on the skeleton would add value to forensic anthropological analysis. This study examines differences in arthritis, osteoporosis, and fracture timing, location, and frequency between individuals with and without arthroplasty. Additionally, differences in trauma frequency are compared based on fixation type. In this study, I hypothesized that those with a joint replacement will show higher rates of arthritis, osteoporosis, and fractures due to the fact that bone quality is usually compromised to some extent to warrant a joint replacement.[1] Additionally, I hypothesized that cemented replacements will demonstrate higher frequencies of fractures than press-fit replacements.

In this study, individuals from the Texas State University Donated Skeletal Collection and the South Texas Applied Forensic Science Center (n=120) were analyzed for the presence of a joint replacement, joint replacement fixation type (cemented or press-fit), arthritis, osteoporosis, and fracture timing, location, and frequency. Additionally, medical records were reviewed to record when the joint replacement occurred. The sample was comprised of an arthroplasty group (n=60) and an age, sex, and Body Mass Index (BMI) -matched control group (n=60). This presentation will highlight the trends of fractures in relation to age, sex, and the presence of joint replacements. To test relationships between recorded trauma and the groups unpaired t-tests were performed on pilot data as the groups were independent and the data followed a Gaussian distribution. A pilot study (n=80) that exclusively examined long bones found that both osteoporosis and fracture rates were higher in the arthroplasty group (8.6% of elements affected versus 5.8% in the control group). Lower leg trauma was the most frequent location trauma in both groups (63% of all fractures). When examining differences within the arthroplasty group, individuals with a press-fit had a higher rate of failure than those with a cemented fit. The finding from the pilot study, though not statically significant (p=0.1946), was surprising, considering a press fit is usually utilized in younger individuals where preoperative bone quality is greater.[1]

Forensic anthropologists should be aware that the chances of trauma increase with arthroplasy when conducting analyses. Additionally, arthroplasty can often result in stress shielding; this differential loading of bone can lead to bone loss and greater fragility.[2]. Understanding if bone changes in individuals with an implant is localized to the affected element or systemic, and when, where, and how fractures occur in elderly individuals can inform trauma analysis for that population and the diagnosis of pathological trauma versus elder abuse.[3].

A31 An Exploratory Analysis of Relationships Between Tibial Diaphyseal Shape and Fracture Outcome

Christopher M. Goden, MA, Injury Biomechanics Research Center, Grove City, OH; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH; Angela L. Harden, PhD, Injury Biomechanics Research Center, Columbus, OH*

Learning Objectives: After attending this presentation, attendees will gain insight into relationships between fracture outcomes and three-dimensional (3D) tibial diaphyseal geometry. This research contributes to an enhanced understanding of skeletal trauma by identifying associations between bone shape and size and fracture outcomes from controlled experiments.

Impact Statement: This presentation will impact the forensic science community by providing novel approaches to identify the influence of 3D tibial diaphyseal morphology on fracture outcomes.

Abstract Text: 3D bone geometry has been associated with fracture susceptibility, but relationships with specific fracture characteristics remain unexplored in forensic contexts.[1] The potential impact of these relationships could alter interpretations and traumatic event reconstructions. Therefore, this study aimed to determine whether variation in tibia shape and/or size exhibited relationships with fracture outcomes in an experimental blunt trauma sample.

Sixty adult tibiae (males [n=29], females [n=31]) were subjected to identical four-point bending experiments at 6 m/s in a lateral-medial direction.[2] Prior to testing, specimens received high-resolution whole-bone Computed Tomography (CT) scans (0.67mm slice thickness; 0.335mm in-plane resolution). Laser surface scans (0.04mm resolution, 0.025mm accuracy) were then acquired for potted diaphyseal specimens, 20–80% of total bone length, to document precise testing orientation. After testing, fractures were classified using the AO/OTA Fracture and Dislocation Compendium, and the total number of fractures per tibia recorded (one [n=31], two [n=19], or ≥three [n=10]).[3] A complexity scheme considering fracture count and combinations of classified fractures was developed to categorize complexity as low (n=22), medium (n=20), or high (n=18).

CT scans were rendered as solid meshes in 3DSlicer then aligned and cropped to match corresponding pre-impact laser scans.[4] A mean tibia was identified through Principal Component analysis (PCA), 1,004 pseudolandmarks were generated on the model and subsequently projected onto the remaining models via thin-plate spline deformation, with placement optimized by 20 anatomical landmarks.[5] Generalized Procrustes analysis and PCA were applied in two configurations: Unscaled (UPC1–10 [98.7% variation]), and Scaled (SPC1–10 [88.7% variation]). UPC1 (88%) reflected length, while UPC2–10 (0.2–3.8%, each) captured diaphyseal size and shape. SPCs (1.4–27.8%, each) represented various aspects of diaphyseal morphology independent of size. Relationships between PCs, fracture count, and fracture complexity were evaluated via multinomial logistic regressions.

Generally, lower UPC scores (4,7) and higher SPC scores (7,8) were associated with a greater number of fractures. While an increase in UPC4 and UPC7 scores reduced the odds of three versus two fractures (OR 0.95, p=0.04; OR 0.87, p=0.01, respectively), higher SPC7 increased the odds of sustaining three versus two fractures (OR 7.08, p=0.02) and higher SPC8 scores increased the odds of three versus one fracture (OR 7.05, p=0.04). Interestingly, higher SPC3 scores reduced the odds of three versus two fractures (OR 0.38, p=0.03) but increased the odds of two fractures versus one (OR 2.07, p=0.02).

Since the associations identified between fracture counts alone and shape are difficult to interpret and do not necessarily reflect fracture complexity (e.g., one fracture can be simple or multifragmentary), further analysis was performed. Higher UPC2 and SPC1 scores decreased the odds of high or moderate complexity versus low (OR 0.55–0.97, p=0.02–0.04). Collectively, lower UPC2 and SPC1 scores may suggest shapes predisposed to more complex fracture outcomes.

Notably, tibia shape variation was observed in the diaphysis, while previous studies have emphasized whole bone shape differences.[6] Prior research has attributed fracture complexity to extrinsic factors, however, this research demonstrated that tibia diaphyseal morphology also contributes to variability in fracture outcomes.[7]

A32 Predicting Blade Width From Saw Marks: The Development and Validation of a Novel Equation

Meghan M. Gast, APM, Des Moines University, Jackson, MS; Alexis L. VanBaarle, APM, Michigan State University, East Lansing, MI; Heather M. Garvin, PhD, Des Moines University, West Des Moines, IA*

Learning Objectives: After attending this presentation, attendees will better understand how Minimum Kerf Width (MKW) can be used to predict blade spine and blade set widths, along with the limitations of such predictions.

Impact Statement: This presentation will impact the forensic science community by providing equations that can be utilized to estimate blade spine and set width, as well as confidence intervals and error rates.

Abstract Text: In cases of saw dismemberment, forensic anthropologists may be asked to provide information about the tool used. The width of incomplete cuts, measured as the MKW, has been shown to correlate with saw blade width. Norman et al. proposed two equations to predict blade width from MKW, but did not report standard errors or provide a method for generating prediction or confidence intervals.[1] This study aims to develop and validate regression models that predict blade width from MKW using a large dataset of incomplete cuts made in human bone with a diverse array of saws.

A total of 376 incomplete cuts were created using 34 saws (17 manual and 17 mechanical). MKW was measured using a stereoscopic microscope, and two linear regression models were developed: one to predict blade spine width and another to predict blade set width. These models were then tested on an independent sample of 48 incomplete cuts made with 8 saws (3 manual, 5 mechanical), different from the reference sample saws. For both the reference and test samples, absolute and relative differences between predicted and actual blade widths were calculated, and the proportion of cases falling within the 95% confidence and prediction intervals was assessed.

MKW was more strongly correlated with blade set width ($R^2 = 0.806$) than with blade spine width ($R^2 = 0.768$), although the spine width model yielded narrower confidence intervals. The spine width model had a Standard Error of the Estimate (SEE) of 0.166 mm, resulting in 95% confidence intervals approximately 0.665 mm wide. In the reference sample, 96.3% of cases fell within this interval, compared to 100% in the test sample. The average absolute difference between predicted and actual spine widths was 0.13 mm for both samples.

The blade set width model had a slightly higher SEE (0.209 mm), producing 95% confidence intervals of 0.836 mm. In the reference sample, 92.6% of estimates fell within this interval, compared to 100% in the test sample. The average absolute error was 0.15 mm for the reference sample and 0.19 mm for the test sample.

Results assessing individual prediction intervals were similar to the confidence intervals and suggest that the use of +/- 2SEE for predictions is adequate with these formulae. For both equations, there was no bias in the reference sample predictions, but there was a tendency to underestimate set and spine width in the test sample (relative bias set = -0.19 and spine = -0.11 mm). This may reflect the fact that the test sample included more hand saws, which tend to have narrower spines, sets, and MKWs and less material wastage. These results suggest that blade width can be predicted from MKW with reasonable accuracy. While the confidence and prediction intervals are relatively wide, the range of set and spine widths exceed the prediction and confidence intervals, thus the equations can be used to exclude incompatible saws with a high degree of confidence.

A33 Skeletal Trauma Analysis in Virtual Modalities: Method Development and Application

Elizabeth M. Paradise, BS, East Carolina University, Raleigh, NC; Christopher A. Wolfe, PhD, East Carolina University, Greenville, NC*

Learning Objectives: After attending this presentation, attendees will be aware of a new tool for scoring blunt force trauma in forensic anthropological casework. Attendees will also learn how this tool can aid the forensic pathologist in a description of the cause or manner of death.

Impact Statement: This presentation will impact the forensic science community by providing a standard scoring system associated with blunt force trauma that can be applied across forensic anthropological contexts. Standardization of skeletal trauma scoring patterns may increase competency in skeletal trauma examination and provide for a more reliable and valid presentation of results in the forensic anthropological case report.

Abstract Text: The analysis of skeletal trauma is a critical component of forensic anthropological practice. However, current research suggests that there is little evidentiary value of skeletal trauma analysis due to its subjective and interpretive methods.[1] The lack of an objective approach to skeletal trauma analysis runs counter to contemporary evidentiary and legal precedent and contemporary trends associated with professionalization and standardization in forensic anthropology.[2] Building from similar standardization trends in the medical sciences, this study adapts the Orthopaedic Trauma Association's 2018 Fracture and Dislocation Classification Compendium (AO/OTA).[3,4] The specialized definitions in the AO/OTA are designed for a clinical context and lack the generalizability to be applied in a forensic examination. Therefore, this study introduces a standardized methodology to objectively score blunt force trauma and assesses the intra- and inter-observer error to determine the reliability and reproducibility of the proposed methodology.

A classification system for the six long bones (humerus, radius, ulna, femur, tibia, fibula) was designed based on images and definitions from the AO/OTA. The classification system is a combination of discrete values corresponding to the bone affected, the location on the bone (e.g., proximal diaphysis), and the type of fracture (e.g., oblique fracture). For example, a score of 3.2.3 would indicate the ulna as the 3rd bone, the proximal diaphysis as the 2nd location, and oblique fracture as the 3rd fracture type. A sample of 133 deidentified individuals were selected from the New Mexico Decedent Image Database.[5] Initial sample selection was completed to gather individuals with a known primary cause or manner of death that suggested blunt force trauma (e.g., beaten by assailant). The associated Computed Tomography (CT) scans were rendered in 3D Slicer and each image was scored twice by the author for intra-observer comparison. Inter-observer comparison was conducted on 30 randomly selected images by ten graduate students. Testing of intra-observer (Cohen's κ) and inter-observer (Fleiss' κ) suggested moderate (0.41-0.60) to substantial (0.61-0.80) agreement as related to the proposed classification system, indicating a valid and reliable method to be applied in forensic practice.

Testing revealed that blunt force trauma can be reliably scored on CT scans based on the proposed approach. Future research will test the reliability of the methodology on dry bone samples. Further, the advent of a standardized methodology moves the field beyond subjective disagreement about interpretation and toward the utility of trauma approaches in more specialized contexts such as the prediction and/or classification of the mechanism of insult.

A34 The Resilience of Cut Mark Characteristics: The Effects of Freezing and Defrosting on Cut Mark Analysis

Mariana Brito, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Giada S. Steiger, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom; James C. Ohman, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will understand how freezing and thawing can alter cut mark characteristics on skeletal remains and the implications this has for sharp force trauma analysis and evidence preservation in forensic investigations.

Impact Statement: This presentation will impact the forensic science community by assessing how freezing and thawing affect sharp force trauma and cut mark characteristics on skeletal remains. It represents a step forward from previous research on cut mark classification by providing new insights into how evidence preservation conditions can influence the reliability of forensic interpretations.

Objective: Freezing and thawing can alter the physical properties of human remains, which is relevant both in cases involving cold environments and when evidence is stored under controlled conditions, such as in morgues.[1] This study investigates how freezing and defrosting procedures may affect the characteristics of cut marks and, consequently, the forensic analysis of sharp force trauma on skeletal remains. The findings aim to inform best practices for cut mark analysis and highlight the potential impact of long-term evidence storage on forensic interpretations.

Methods: For this experiment, 12 bones of pig ribs (*Sus scrofa*) were used to simulate the human bone's structure. Ten cuts were inflicted on each bone in one forth-and-back motion using a single-bevelled, micro-serrated kitchen knife that was used in prior research related to guaranteeing uniformity and reliability.

The cut marks were analysed under a stereomicroscope at 4.73-7.5x magnification and assessed according to six traits previously proposed as diagnostic for identifying serrated versus non-serrated implements: (1) shape of the cut mark; (2) cross-profile shape; (3) rising; (4) feathering; (5) bone shards; and (6) mounding.[2]

After the initial analysis, the ribs were divided into two groups and placed during a two-week period in freezers at -20ºC\-4°F and -78ºC\-108°F. One tray from each group was defrosted in a gradual method, passing from freezer to fridge (5°C\41°F) and finally room temperature (21ºC\70°F), while the other trays suffered a drastic defrosting process, passing directly from freezer to room temperature. After the thawing process, the cut marks were re-observed using the same criteria for the traits' description.

Results: The study revealed that the majority of traits (e.g., shards, feathering, and cross-profile shape) are not affected by the freezing and defrosting procedures. However, traits such as shape, mounding, and rising are more susceptible to changes. For instance, concerning shape, there was a 10% increase in a specific feature after freezing and defrosting. Moreover, certain features in mounding showed alterations by 26.95% and 29.68% before and after freezing and defrosting. Lastly, rising displayed alterations in all features, with single and bilateral rising increasing by 17.64% and 18.80%, respectively, after freezing and defrosting. This is possible to observe due to systematically analyzing and recording the observability and alterations of the traits prior and after freezing and thawing. Moreover, by applying a side-by-side comparison of the observability of traits percentages recorded, it is possible to analyze its resilience/survivability. Only minor fracturing and an increase of porosity have been observed on a small number of cut marks; however, these alterations did not affect the interpretation of the lesions.

Conclusion: This study demonstrates that most characteristics used in cut mark analysis are resilient against different freezing and thawing temperatures, even if the defrosting process is quite drastic and happens relatively quickly. However, some alterations are observed on traits such as shape, mounding, and rising, suggesting the need for future evaluation of storage/thawing protocols for cut mark evidence.

A35 An Overview of Blunt Force Perimortem Trauma in a Sample of Decedents From the Texas-Mexico Border

Chris L. McMillan, BS, Texas State University, San Marcos, TX; Victoria S. Soto, MA, Texas State University, Courtney C. Siegert, PhD, Texas State University, San Marcos, TX; Victoria Swenson, PhD, Operation Identification, San Marcos, TX; Chloe P. McDaneld, MA, Texas State University/Operation Identification, San Marcos, TX; San Marcos, TX; Abigayle Jose, BA, Operation Identification, San Marcos, TX*

Learning Objectives: After attending this presentation, attendees will have a greater understanding about the prevalence and type of blunt force perimortem trauma in a sample of migrants from the Texas-Mexico border.

Impact Statement: This presentation will impact the forensic science community by informing attendees about the prevalence and type of blunt force perimortem trauma seen in a sample of decedents who died along the United States-Mexico border, an underserved community in United States death investigation.

Abstract Text: Migrant deaths have been steadily increasing for the past 30 years along the United States-Mexico border despite "Prevention Through Deterrence" policies that were adopted during the Clinton administration to discourage migration into the United States. For the past 13 years, Texas has surpassed Arizona in having the highest number of migrant deaths[1].

Operation Identification (OpID) was established in 2013 as a forensic humanitarian initiative aimed at identifying unidentified human remains who died along the Mexico-Texas border. OpID has assisted law enforcement authorities and other medicolegal agencies with death investigation and forensic case management for over 700 cases of unidentified human remains, including cases that were transferred to OpID to identify and repatriate presumed migrants (N=492). Many migrant fatalities in the borderlands are often the result of exposure, dehydration, drowning, and traumatic events.

There are 15 cases that have observed perimortem Blunt Force Trauma (BFT). Fracture patterns observed comprised a high number of cranial, forearm, and lower limb trauma. The objective of this study is to highlight three cases of perimortem BFT of presumed migrants. The first case demonstrates extensive perimortem trauma to multiple regions of the skeleton. The second case describes perimortem trauma that was sustained through vertical deacceleration from a great height. The last case demonstrates a single perimortem fracture to a long bone, which is representative of most cases of perimortem trauma observed at OpID.

The objective of this presentation is to demonstrate blunt force perimortem trauma seen in a sample of migrant populations. The information found within this presentation can inform readers about types of perimortem trauma observed at the Texas-Mexico border while facilitating discussion about interpretation of the perimortem interval through skeletal analysis.

The objective of this presentation is to demonstrate blunt force perimortem trauma seen in a sample of migrant populations. The information found within this presentation can inform death investigators about perimortem trauma and help shape future investigations at the Texas-Mexico border.

A36 Art or Science? Using FADAMA to Assess the "Art" of Synthesizing Skeletal Age-Interval Estimates

Sophia Henn, BA, University of West Florida, Fisherville, FL; Phoenix Farnham, BA*, University of West Florida, Pensacola, FL; Allysha P. Winburn, PhD, University of West Florida, Pensacola, FL*

Learning Objectives: After attending this presentation, practitioners will learn the benefits and detriments of generating multiple-method skeletal age-range estimates based on three different approaches: creating a broad range inclusive of the age ranges from all utilized methods; creating a narrow range based on the highest lower-age terminus and the lowest upper-age terminus of all estimated ranges; or using a generalized, experience-based approach.

Impact Statement: This presentation will impact the forensic science community by providing accuracy data that will inform anthropologists' decisions about synthesizing multi-method age ranges. In the absence of a statistically valid way to combine age estimates from different methods, how might practitioners maximize accuracy while minimizing subjectivity?

Abstract Text: Once described as "an art, not a precise science," skeletal age estimation has become increasingly standardized.[1,2] However, there is no disciplinary consensus on how to produce age-interval estimates when multiple methods are utilized. Should a range be synthesized, regardless of the methods' internal statistics? If so, should it be broad and conservative, with a minimum based on the "lowest low" of all age ranges and a maximum based on the "highest high"—or narrower, informed by the "highest low" and "lowest high?" Generalized, experience-based approaches to generating age-estimate intervals often prove accurate and reliable results.[3,4]

Should practitioners merely craft a range based on experience? This study used a sample of anonymized, identified Forensic Anthropology Database for Assessing Methods Accuracy (FADAMA) cases in which skeletal age was estimated and chronological age was known (n=481) to investigate the accuracy (estimated range includes chronological age) of three approaches to age-range generation: (1) using the experience-based range reported by the original analyst; (2) synthesizing a range based on the "Lowest Low and Highest High" (LL-HH); and (3) synthesizing a range based on the "Highest Low and Lowest High" (HL-LH).[5] Results were parsed by sex (females [n=127], males [n=350]); age (younger [n=265], middle [n=145], and older adults [n=71]); and race (Asian/Pacific Islanders [n=15] and Black [n=78], Hispanic [n=115], Native [n=16], and White Americans [n=216]).

Experience-based age ranges were consistently accurate—88% overall—ranging from 85% in Black Americans to 100% in Asian/Pacific Islanders. Accuracy was even higher using LL-HH ranges—94% overall—ranging from 90% in older adults to 100% in both Asian/Pacific Islanders and Native Americans. In contrast, HL-LH accuracy was low (< 60%) in all groups but one, averaging 56% overall and ranging from 44% (older adults) to 94% (Native Americans). Further, in 10% of cases, HL-LH ranges were internally contradictory (lower terminus higher than upper terminus) and could not be used. The five methods most frequently reported by analysts included "generalized morphology," Brooks and Suchey, İşcan et al., Langley-Shirley and Jantz, and Meindl and Lovejoy—the latter an unexpected finding given the distrust of cranial sutures expressed by many practicing forensic anthropologists.[4,6-10]

These results are consistent with research indicating that, though subjective, experience-based forensic anthropological age estimates are largely accurate.[3,4] Findings also indicate that extremely high accuracy can be achieved by using the "lowest low" and "highest high" estimated by all utilized methods. These LL-HH age ranges can be extremely broad: of the 272 cases that yielded an upper terminus, the average age-range length was 32.6 years; for the remaining cases, the "highest high" merely constituted a cut-off (e.g., 60+), ensuring that any chronological age above that point would be included in the estimate. Still, in absence of a statistically valid way to combine age estimates from disparate methods, and for those practitioners uncomfortable with the "art" of using experience-based approaches, LL-HH provides a way to maximize accuracy while minimizing subjectivity. In contrast, HL-LH ranges are inaccurate, often internally contradictory, and should not be used.

A37 Considering the Biological Profile in 2026: Accuracy and Relevance in the Current Age

Chelsey A. Juarez, PhD, California State University Fresno, Fresno, CA; An-Di Yim, PhD, George Mason University, Manassas, VA; Cris Highes, PhD, University of Illinois Urbana-Champaign, Urbana, IL*

Learning Objectives: In this study, we cover the latest data from the Forensic Anthropology Database for Assessing Methods Accuracy (FADAMA) on method and case level accuracy for all components of the biological profile.

Impact Statement: Attendees to this presentation will gain an understanding of the current accuracy of our methods at both the case and method level. Including methods that are outperforming case level accuracy rates. In addition, attendees will understand the latest discussion around relevancy of the biological profile in the face of DNA advances

Abstract Text: Using data from the FADAMA (n = 641 cases), we investigated two levels of accuracy in the practice of biological profile estimations: case-level (the accuracy of each estimated component of the biological profile as described in the case report produced by the forensic anthropologist) and method-level (the accuracy of a given method used in a case). For case-level accuracy, we found that both population affinity and sex were above 90% but remained lower for stature (83%) and age estimation (89%). Whenever possible, in case-level accuracy, each category of the biological profile was investigated for the impacts of sex and race. Interestingly, despite the high rates for case-level accuracy for sex, when the case-level accuracy rates for identified females and males were compared, females were more likely to be incorrectly estimated than males (Fisher's exact $p = 0.0047$). For method-level accuracy, we found mixed results. Method-level accuracy for the top ten most commonly used sex estimation methods present in the FADAMA sample was at or above 97% for all ten methods. On the other hand, method-level accuracy for the top 15 age estimation methods ranged from 54% to 100%, with only 5 out of 15 studied methods at or exceeding case-level accuracy.

Top performing age estimation methods which met or exceeded case level accuracy included Brooks & Suchey, Langley-Shirley & Jantz, Webb & Suchey, Osborne et al., and Transition Analysis/ADBOU (Boldsen et al.).[1-5] Method-level accuracy for stature estimation ranged from 35% to 88.5%, with only one of three studied methods exceeding case-level accuracy (FORDISC, Jantz & Ousley).[6] Method-level accuracy for population affinity methods ranged from 81.4% to 90.5%, with no methods outperforming case-level accuracy. We concur with Hughes and colleagues that this disconnect between case-level and method-level accuracies clearly demonstrates the importance of practitioner synthesis and interpretation of method outcomes as well as the influence of multiple methods being used in combination, resulting in the generally higher accuracies at the case-level.[7]

Given the high case-level accuracy rates for sex and population affinity estimation (98.9% and 93.6%, respectively) found in this study, the two categories most commonly investigated by DNA, we agree with Thomas et al. and others who have found similar patterns, that forensic anthropological estimation of these components of the biological profile continues to make sense even with recent advancements in DNA technologies.[8] Furthermore, not all state forensic DNA laboratories are equipped to handle degraded DNA samples from bone, and very few public laboratories are processing DNA samples for variants used in genetic ancestry estimations as part of their standard workflow. Thus, ancestry estimations from DNA are not common enough (and even when performed have slow turnaround times) to negate the utility of the forensic anthropologist's estimation of population affinity in an unidentified persons investigation.

A38 Evaluating Accuracy and Precision: A Comparison of Transition Analysis to Traditional Age-At-Death Estimation Methods

Allyson M. Simon, MS, The Ohio State University, Columbus, OH; Conner I. Gayagoy, The Ohio State University, Columbus, OH; Dawnie W. Steadman, PhD, University of Tennessee, Knoxville, Knoxville, TN; Colleen M. Cheverko, PhD, Rush University, Chicago, IL; Mark Hubbe, PhD, The Ohio State University, Columbus, OH*

Learning Objectives: From this study, the audience will learn about the difference in accuracy and precision of common age-at-death estimation methods. This study shows that age-at-death estimation methods have larger average absolute errors and tend to underestimate age at death, demonstrating the inherent limits in our ability to quantify to process of skeletal aging.

Impact Statement: This presentation will impact the forensic science community by demonstrating the limits, accuracy rates, and precision of different age-at-death estimation methods using a modern sample. The results add to previous literature by demonstrating the large average absolute error of methods, and their general tendency to underestimate age at death. Of special impact, our result show that statistically advanced methods, like Transition Analysis, do not substantially outperform traditional methods in this sample.

Abstract Text: Age-at-death estimates are an essential component of the biological profile, used to narrow possible identification in medicolegal contexts. Traditional methods dominate professional practice due to their accessibility and familiarity in forensic anthropology.[1] Despite their high applicability, no standardized and statistically valid way to combine age ranges from these methods exists, and some researchers suggest relying on experience when establishing the final estimate.[2] To address this limitation, a multifactorial method was developed by Boldsen et al., Transition Analysis (TA). Using this method, researchers score the pubic symphysis, iliac auricular surface, and cranial sutures according to the TA manual and input the scores into ADBOU to generate age estimates for individuals. This study compares traditional methods with TA to answer the following questions: (1) does TA provide more accurate age-at-death estimates than traditional methods, and (2) how do age estimation methods vary in their accuracy and error from known age at death?

This study used a randomly selected sample (n = 95) from the University of Tennessee, Knoxville Donated Skeletal Collection. The following age estimation methods were applied to each individual when necessary anatomical regions of the skeleton were available: Transition Analysis, Suchey-Brooks, Hartnett, Lovejoy et al., Buckberry and Chamberlain, and Meindl and Lovejoy.[3-9] The accuracy of each method was evaluated by whether the known age fell within the estimated age interval. The method's tendency to over- or underestimate age (bias) and distance from the known age (absolute error) were also calculated. Precision was measured as the breadth of the confidence interval.

Analysis of Variance (ANOVA) and Tukey tests were conducted to test for differences in bias and absolute error across methods. Results showed that TA performed moderately across error metrics having significantly higher bias than Buckberry and Chamberlain ($p < 0.05$), but lower absolute error than Meindl and Lovejoy's vault suture estimates ($p < 0.05$). Comparisons against other methods displayed no significant differences. A paired t-test was conducted to compare the point estimate of TA to the known age the individuals. The test revealed a significant underestimation of age at an average of 12.62 years (95% CI: 8.78-16.46, $p < 0.001$). The overall accuracy for TA was 49.47% and the confidence interval had an average range of 28.81 years. In this study, the most accurate method was Buckberry and Chamberlain (accuracy rate: 90.36% to 92.86%), followed by Suchey-Brooks (80.77% to 83.33%). However, higher accuracy was achieved through lower precision with an average CI width of 49.2 years for Buckberry and Chamberlain and 43.32 years for Suchey-Brooks. In conclusion, TA did not perform significantly better than traditional age estimation methods in this sample, suggesting that multifactorial methods do not necessarily yield more accurate and precise results. Moreover, this study further corroborates that traditional methods have high absolute errors and tend to underestimate age for middle- and old-aged adults.

A39 Testing Non-Adult Age Estimation Methods on a Contemporary Taiwanese Sample

Kara Becker, George Mason University, Kingston, MA; An-Di Yim, PhD, George Mason University, Manassas, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the accuracy of different age estimation methods used for non-adult individuals as they apply to the Taiwanese population.

Impact Statement: This presentation will impact the forensic science community by contributing to studies on accuracy and precision of non-adult age estimation methods, allowing these methods to be widely applied to practical settings. Moreover, this presentation contributes to the increased ability to properly identify non-adult individuals as well as encouraging improvement within the methods used in the field.

Abstract Text: There are many different methods of age estimation for non-adult individuals. These methods were developed using mostly European groups and thus vary in their application. Specifically, East Asian groups are relatively underrepresented in forensic anthropology literature compared to other groups around the world. This study seeks to test different long-bone dimensions-based methods of non-adult age estimation for a Taiwanese sample.

Computed Tomography (CT) scans of individuals aged 0 to 16 years old of both sexes were collected from the National Taiwan University Hospital (NTUH), totaling 117 individuals. Different long bone measurements, including diaphyseal length and proximal and distal breadths, were taken from the CT scans. Six methods were tested: the MCP-S-Age interface, Scheuer et al., Cardoso et al., Facchini and Veshci, Lopez-Costas et al., and Rissech et at., used in conjunction with Rissech et al.[1-7] Point estimates and age ranges were separately compared to the true age of the individuals to determine if the true ages fall within the estimated range (accuracy) and estimate bias and inaccuracy of each method. Bias was calculated by averaging the differences between the point estimate and true age, while inaccuracy was calculated by averaging the absolute differences between the point estimate and the true age.

Newer methods, such as the MCP-S-Age applications provided significantly better accuracy than older methods (accuracy for MCP-S-Age: 82.64%, the other methods have accuracy rates as low as 47.01%). Compared to other methods, the MCP-S-Age software also has less inaccuracy and bias, with an average inaccuracy of 2.37 years. However, due to the biases from the reference populations, there was a tendency for the age estimations to fall below the true age for the MCP-S-Age estimations. Residual plots showed varying trends of inaccuracy as age increases for different methods. The results from this study indicated that for Taiwanese non-adult individuals, the most appropriate method for age estimation using long bone dimensions is the MCP-S-Age software.

A40 Age-Informative Features of the Sacral Auricular Surface

Krista E. Bennett, PhD, SNA International, Honolulu, HI*

Learning Objectives: After attending this presentation, attendees will better understand the relationships between age-related features of the sacral auricular surface and which of these features can best aid in adult age-estimations

Impact Statement: This presentation will impact the forensic community by providing revised and newly developed descriptions and an expanded scoring system for age estimation of the sacral auricular surface.

Abstract Text: While various adult age estimation methods exist, forensic anthropologists commonly employ methods using features of the os coxae, including the pubic symphysis and the auricular surface of the ilium.[1-5] Although the sacral auricular surface of the sacrum reflects degenerative change associated with advanced aging, it is rarely analyzed. To date, only one age-at-death method has been developed for the sacrum, offering age ranges with 68% or 95% confidence intervals.[6] However, the method employs a complex coding system and reports weak relationships between traits and age.[7] Moreover, due to anatomical differences in the surface cartilage, the sacral auricular surface appears approximately two decades younger compared to the auricular surface of the ilium.[6,8,9] Therefore, to improve age estimation from the sacrum, this study applied features described in the Passalacqua method alongside revised and newly developed descriptions and an expanded scoring system to evaluate if stronger relationships between features and age could be established.

A total of 560 sacra (302 males and 258 females, 18–102 years) were examined. Six features were scored including: auricular surface texture, fusion of the first sacral segment (S1) ring, microporosity and macroporosity on the auricular surface, changes to the auricular surface rim, and lipping around S1. Each feature was scored categorically depending on the degree of change observed on the feature of interest as one, two, or three. For example, a score of one for micro- and macro-porosity meant neither were present, a score of two if either were present on one half of the surface (divided at the apex), and three if either was present on both halves. Other features, such as lipping around S1, received of a score of one where no lipping was present, two where minimal lipping was present (1–3 mm), or three where > 3mm of lipping was present. Individuals were separated into decadal groups to aid in assessing relationships between features and age. Pearsons's correlations were conducted to assess whether statistical relationships exist between sacral features and age groups.

All features selected exhibited positive correlations with increasing age ranging from weak (e.g., surface texture [r=0.26]) to moderate (e.g., lipping around the first sacral segment [r=0.49]). Additionally informative trends were observed between features and age groups, including the presence microporosity on both halves the auricular surface doubling in the sample and >3mm of lipping around S1 occurring in ~50% of the sample by the seventh decade of life. These findings suggest that while sacral auricular surface features individually show weak to moderate correlations with age, their combined assessment—particularly with features like lipping of S1 and microporosity—may enhance the utility of the sacrum in age-at-death estimation, offering a promising avenue for future methodological refinement in forensic anthropology.

A41 Developing a Radiographic Application of the Lamendin Method: A Non-Invasive Dental Aging Technique for Forensic Identification

Devin N. Williams, MA, North Carolina State University, Raleigh, NC; Ann H. Ross, PhD, North Carolina State University, Raleigh, NC*

Learning Objectives: Attendees will learn about the application of a non-invasive radiographic technique for dental age estimation and its advantages over traditional methods requiring maceration, tooth extraction, or specimen destruction. The presentation will cover preliminary findings supporting the feasibility of adapting the Lamendin method to digital radiographs. Attendees will also gain insight into the method's practical use in forensic casework, particularly in contexts involving unidentified remains and mass fatalities.

Impact Statement: This study enhances the competence of forensic practitioners by introducing a validated, radiographic method for age-at-death estimation that minimizes the need for invasive procedures. By addressing the influence of substance abuse and systemic health conditions on dental aging markers, the project improves performance in casework involving vulnerable populations. The findings have the potential to strengthen victim identification efforts in mass disasters and forensic contexts, particularly when traditional skeletal assessments are not feasible.

Abstract Text: Age-at-death estimation is a foundational component of the biological profile in forensic anthropology and plays a critical role in identifying unidentified decedents, especially in mass disaster contexts. While skeletal and dental assessments are widely used, dental radiographs remain an underutilized tool for age estimation, despite their widespread availability, portability, and non-invasive nature. The Lamendin et al. method, which relies on direct measurements of single-rooted teeth, has been adopted internationally for age estimation.[1] However, its application to dental radiographs has not been systematically evaluated. Furthermore, the accuracy of this method may be influenced by chronic drug and alcohol use, yet these effects remain unexplored.

This research aims to validate a cost-effective, dental radiographic adaptation of the Lamendin method and evaluate its reliability. Specifically, we will assess whether radiographic measurements of root height, dentinal translucency, and periodontitis correspond to direct physical measurements taken from extracted teeth. We will also examine how chronic substance use and associated health conditions may compromise the accuracy of these dental aging parameters.

A pilot study was conducted using a small sample of individuals from the North Carolina State Forensic Analysis Laboratory to compare direct and radiographic measurements of single-rooted teeth. Paired t-tests (n=15) showed no statistically significant differences between the direct physical measurements taken from extracted teeth and radiographic measurements (*p-value* = 0.092, 0.131, and 0.626, respectively). Loess regression analyses (n=19) confirmed a linear relationship between age and translucency, while periodontitis exhibited a more complex relationship with age, increasing in older individuals but also present in some younger individuals, suggesting that lifestyle and health factors may affect its progression independently of age.

Future research will expand this preliminary work to a larger sample of 300 individuals. Dental radiographs will be obtained during autopsies using a handheld X-ray unit, and measurements will be recorded using dental imaging software. These radiographic data will be directly compared to measurements from the same teeth after extraction, allowing evaluation of method reliability. In addition, toxicological analysis of autopsy specimens will be conducted to verify substance use history. This research addresses a critical methodological gap in forensic science by evaluating whether dental radiographs can serve as a reliable alternative to tooth extraction. Ultimately, this work aims to improve the accuracy, reproducibility, and practicality of the Lamendin age-at-death estimation method by integrating digital radiography and assessing the impact of substance use on dental aging parameters.

A42 A Test of the Accuracy of Skeletal Age Estimation Methods on a Modern South-Central United States Population

Alexandra L. Aaberg, BS, Louisiana State University Forensic Anthropology and Computer Enhancement Services (FACES) Laboratory, Baton Rouge, LA*

Learning Objectives: The goals of this presentation are to evaluate the performance of five age estimation methods, assess the effects of combining multiple methods, and examine how chronological age influences method accuracy. This study focuses on comparative accuracy both between and within methods using a modern population from the South-Central United States.

Impact Statement: This presentation will impact the forensic science community by critically evaluating age estimation methods and identifying those that yield the most accurate results. These findings aim to inform best practices in forensic anthropological casework, as understanding the efficacy of age estimation methods in this region and across age groups is essential to improving the identification of unknown decedents.

Abstract Text: Age estimation is a key component of the forensic anthropological profile used in the identification of unknown human remains.[1] Adult age estimation methods typically assess degenerative changes in skeletal indicators, such as the pubic symphysis, iliac auricular surface, and sternal rib ends, which exhibit relatively predictable changes over time. However, variation in physiological aging, biomechanical factors, and lifestyle introduces uncertainty, prompting forensic anthropologists to rely on both point estimates and age intervals when assessing the age of a skeleton.[1-3] Despite the number of available methods, comparative performance and standardized approaches for combining multiple methods remain limited.[1]

This study evaluates the accuracy of Hartnett's revised methods for the right and left sternal ends of the fourth rib and the pubic symphysis, as well as Transition Analysis 2 (TA2) for the pubic symphysis and iliac auricular surface, both individually and combined.[2,4-6] Data was collected from the Southeast Texas Applied Forensic Sciences (STAFS) Skeletal Collection at Sam Houston State University (donations from 2009–2021; N=151; 76 male; 75 female; mean age = 53.6; range 18–88). The sample was divided into four age groups: 18-35 (N=12), 36-50 (N=45), 51-65 (N=74), and 66+ (N=20). For each individual, average point estimates and maximum and minimum intervals were compiled.

Classification accuracy was defined as an individual's reported age at death falling within a method's 95% confidence age interval (±2 SD from the point estimate). The combined maximum interval yielded the highest classification accuracy (95.4%), followed by TA2 of the iliac auricular surface (82.6%) and TA2 of the pubic symphysis (76.2%). The least accurate methods were the composite minimum interval (31.1%) and Hartnett's sternal rib end method (49.0%). Classification accuracy was lowest in the 66+ group across all methods, with statistically significant decreases seen in Hartnett's pubic symphysis (40%, $p=0.001$) and rib (10%, $p< 0.001$) methods.

All methods tended to underage individuals, reflected in negative bias scores.[7] TA2 of the pubic symphysis and iliac auricular surface showed the least bias (-2.458 and -3.336, respectively), while the combined TA2 point estimate significantly underestimated age (-9.39, $p< 0.05$). Of the methods used, bias differences between the four age groups were statistically significant ($p=0.22$), in which most methods tended to underage all age groups except the youngest (18-35), who were overaged. An exception was the 36–50 group in TA2 pubic symphysis, which was slightly overaged.

Overall, this study addresses a gap in understanding the comparative performance of age estimation methods in a regional sample from the South-Central United States. The results support the use of methods such as a combined point estimate/maximum interval, TA2's iliac auricular surface, and TA2's pubic symphysis, based on both their high classification accuracy and point estimate proximity to true age at death. However, practitioners should be mindful of method specific biases, especially their tendency to underage older individuals and overage younger individuals when applying these methods. Future studies should be done to determine the impact of other population demographics, such as sex, ancestry, and lifestyle, to refine age estimates and improve method utility in forensic casework.

A43 A Test of the Cameriere et al. Pulp/Tooth Area Age Estimation Methods in a United States Population

M. Biannet Perez, MA, Binghamton University, Johnson City, NY; Kailee Behunin, BA, Binghamton University, Binghamton, NY; Alexandra Semma Tamayo, MSc, Binghamton University, Binghamton, NY; Laure Spake, PhD, Binghamton University (SUNY), Binghamton, NY; Cai Caccavari, MA, Binghamton University, Binghamton, NY; Nolan M. Robinson, DDS, Vestal Dental Associates,Vestal, NY*

Learning Objectives: This presentation highlights the benefits and limitations of Cameriere's pulp/tooth area ratio method for age estimation in United States adults. We highlight key limitations such as observer-dependent accuracy and poor performance in younger and older age groups. The research aims to support practitioner competence and support more reliable age estimates in forensic casework

Impact Statement: This presentation will impact forensic science by providing evidence on the limitations of Cameriere's pulp/tooth area ratio method for age estimation in United States adults. This presentation will enhance practitioner competence by highlighting the method's observer-dependent accuracy and poor performance in younger and older age groups. This presentation will show its support for more reliable age estimates, benefiting forensic investigations and the families of the deceased.

Abstract Text: Estimating the age of adults aged over 50 years is challenging. The pulp-to-tooth ratio method by Cameriere et al. has yielded promising results for adult age estimation in various populations, but has not been evaluated for use in a United States context. This study evaluated the repeatability and validity of the Cameriere et al. method in a contemporary United States sample of 146 individuals (69 males and 77 males aged 18-95).[1,2]

Images of a total of 136 mandibular canines, 89 first premolars, and 82 second premolars were obtained from Cone Beam Computed Tomography (CBCT) scans. Teeth with root canal therapy and fillings obstructing the pulp area were excluded from the sample, but those with small fillings and mild dental wear were included to reflect variation found in forensic casework. Three images of each tooth were taken in a buccolingual orientation using different slab thickness (0.85 mm to 1.18 mm) using Dragonfly ORS v.2024.1.[3] Afterward, images were exported to the open-source vector graphics editor Inkscape v.1.4.[4] The Bezier curve tool was utilized to mark a maximum of 20 points for each tooth outline and pulp cavity, from which measurements of the tooth and pulp areas were calculated in square pixels (px^2).

To evaluate the method's repeatability, intra- and inter-observer measurements were performed on 20 canine and 20 premolar images. Three observers with varying levels of experience measured the full tooth area and pulp cavity on all 40 images three separate times. Intra- and inter-observer reliability were evaluated by calculating the Technical Error of Measurement (TEM), relative TEM (rTEM), and Intra-class Correlation Coefficients (ICC). Whole tooth area measurements showed acceptable repeatability; however, pulp cavity measurements exceeded acceptable error thresholds. Intra-observer error was lowest for the observer with more years of experience in forensic anthropology than for those with fewer years of experience, suggesting that observer experience is crucial in the repeatability and potentially validity of the Cameriere methods.

To evaluate the method's validity, the ratio of the pulp-to-tooth area was calculated using equations provided by Cameriere et al., and 95% prediction intervals were calculated by adding and subtracting twice the standard error of the estimate for each of the equations.[1,2] Accuracy and bias was assessed by calculating the mean residual, mean absolute residual, and the percentage of individuals whose true ages fell within the 95% prediction interval. Overall method performance ranged from 48–57% of individual true ages falling within the 95% prediction interval, and mean absolute residual ranged from 13.5 to 15.4 years. Error was generally patterned by age, with overestimation of age in individuals under 30 years and underestimation in individuals over 60 years of age. Dental wear also had an impact on age estimation accuracy: age tended to be more dramatically underestimated when teeth showed wear.

Findings from this research suggest that practitioners should exercise caution when applying this method to forensic casework in the United States, particularly in instances where dental wear is present.

A44 Addressing Asymmetry in Phase-Based Age Estimation Methods

Allyson M. Simon, MS, The Ohio State University, Columbus, OH; Conner I. Gayagoy, The Ohio State University, Columbus, OH; Dawnie W. Steadman, PhD, University of Tennessee, Knoxville, Knoxville, TN; Colleen M. Cheverko, PhD, Rush University, Chicago, IL; Mark Hubbe, PhD, The Ohio State University, Columbus, OH*

Learning Objectives: In this presentation, participants will learn about the impact of skeletal asymmetry when applying phase-based age estimation methods. Different strategies for addressing cases of side disagreement in phase assignment are evaluated, ultimately showing that one strategy does not outperform others due to considerable individual variation in skeletal aging.

Impact Statement: This presentation will impact the forensic science community by demonstrating that the factors underlying skeletal asymmetry in aging are highly variable, thus complicating our ability to address asymmetry in the application of age estimation methods. Given such variability, we recommend a conservative approach of combining age ranges in cases of phase disagreement between sides.

Abstract Text: Macroscopic phase-based age estimation methods are frequently applied in forensic anthropology casework to assist in narrowing down potential identifications. Most phase-based age estimation methods can be applied bilaterally, that is, to anatomical regions of the left or right side of the skeleton. Although some methods specify that practitioners should examine the left side, it is generally assumed that the right side should be substituted when the left side is unavailable and vice versa. However, when anatomical regions of the left and right side are both available, bilateral anatomical regions may reflect different biological ages, and thus fit the criteria for different phase assignments. Some practitioners may report combined ranges or where the ranges overlap, although these approaches have not been tested or validated.[1] Previous findings have shown side disagreement can affect over 60% of individuals in some samples, with differences in reported age ranges between sides typically between 10–15 years.[2,3] Consequently, asymmetry in skeletal aging, and how practitioners address it in their application of age estimation methods, affects age estimation outcomes. This research addresses the following questions: (1) What is the frequency of side disagreement when applying phase-based age estimation methods of the pubic symphysis, iliac auricular surface, and sternal rib ends? Are there sex-based differences in these frequencies? (2) How does side disagreement affect accuracy rates? In cases of side disagreement, is the younger or older phase consistently more accurate? Are ranges that combine both phases more accurate?

These questions were evaluated on a sample selected randomly from the University of Tennessee Knoxville, Donated Skeletal Collection, stratified for sex and age (n=100). For each individual, the following phase-based age estimation methods were applied bilaterally: Brooks & Suchey, Lovejoy et al., and İşcan et al.[4-7] The frequency of side disagreement between phases was calculated for the total sample and separately for males and females. Differences in accuracy rates based on phase differences in cases of side disagreement were analyzed.

Rates of side disagreement were not significantly different between methods ranging from 24.4% with Suchey-Brooks, 30.2% with Lovejoy, and 20% with İşcan. However, there was a significant association between asymmetry of the iliac auricular surface and the pubic symphysis ($\chi^2 = 26.529$, $p < 0.001$), showing that individuals with asymmetry in one of these anatomical regions are more likely to have asymmetry in the other. There were no sex-based differences in side disagreement rates for any of the methods analyzed. When evaluating differences in accuracy using differing strategies for addressing cases of side disagreement, there was no consistent trend favoring the younger phase, older phase, combined phases, or overlapped phases for any method analyzed. These results suggest that one strategy does not result in significantly higher accuracy rates than others due to individual variation in skeletal aging. Combining phases is recommended as the most conservative approach to address side differences in the application of age estimation methods, although this approach results in broader age ranges.

A45 A Validation of the CADOES Method on a Taiwanese Sample

Madison A. Glenwinkel, BA, Texas State University, Maxwell, TX; Elaine Y. Chu, PhD, Texas State University, San Marcos, TX; Shuo-Yen Lin, MCS, Big Data Center, Taichung, Taichung, Taiwan; Michael Anekson Widjaya, PhD, China Medical University Hospital, Taichung, Taichung, Taiwan; Hung-Lin Chen, PhD, China Medical Univeristy Hospital, Taichung city, Taichung, Taiwan; Chin-Chi CC Kuo, PhD, Big Data Center, China Medical University Hospital, Taichung City, Taichung, Taiwan*

Learning Objectives: This poster will provide viewers with an understanding of population-specific sexual dimorphism in the pelvis by evaluating how well the Classification of Osteometric Data for Estimation of Sex (CADOES) method of sex estimation, developed on a Portuguese sample, performs when applied to a Taiwanese sample.

Impact Statement: This presentation will impact the forensic science community by demonstrating how population specificity and sample diversity are important factors to consider when developing or applying forensic anthropological sex estimation methods.

Abstract Text: In forensic anthropology, the pelvis is acknowledged as the truest indicator of sex due to its high degree of sexual dimorphism in both size and shape.[1] However, sexual dimorphism of the pelvis has been shown to be population specific, and thus sex estimation methods are not equally accurate across all populations.[2] Most methods were developed on individuals of European and African descent, which are populations that tend to exhibit more pronounced sexual dimorphism than populations of Asian or Hispanic descent.[3] As such, these methods are often less accurate for Hispanic and Asian populations.[4]

This project has two objectives: (1) to evaluate the accuracy of the CADOES sex estimation method on a Taiwanese sample (N=40), and (2) to compare the magnitude of sexual dimorphism in a Taiwanese sample to the original Portuguese sample data (N=240) from which CADOES was developed.[5,6]

Three-Dimensional (3D) pelvis models were provided by China Medical University Hospital iHi data platform.[7] Landmarks were placed on 3D models to assess 11 CADOES-defined measurements: coxa height (AMB), left and right iliac thickness (Ele and Eld), distance between the posterior superior iliac spines (LBPS), distance between the anterior superior iliac spines (LBAS), distance between the lateral margins of the ischial tuberosities (DIEn), greatest distance between the arcuate lines (LME), maximum pelvic width (LMP), distance from the sacral promontory to the posteroinferior point of pubic symphysis (CD), distance from the sacral promontory and anterosuperior margin of the pubic symphysis (CA), and distance from the sacral apex to the inferior point of the pubic symphysis (DSSB).

Sex was estimated for the Taiwanese sample (M=20, F=20) using all 11 measurements within a Linear Discriminant Analysis (LDA) model. For population level analyses, the Portuguese sample was randomly divided into 6 groups of 20 males and 20 females to match the Taiwanese sample size and avoid class imbalance in statistical analyses. Kruskal-Wallis and Dunn's tests were conducted to test for statistically significant differences ($\alpha = .05$) between groups for each measurement.

The LDA model accurately estimated sex for 100% of Taiwanese males and for 75% of Taiwanese females. All males were estimated with a posterior probability of 1.00, while females were estimated with posterior probabilities ranging from 0.01 to 1.00, (mean=0.73; median=0.91). Population level analyses showed that the Taiwanese sample was statistically larger than the Portuguese sample in four measurements (CA, LBPS, Eld, Ele) and significantly smaller than the Portuguese sample in one measurement, DSSB. The median difference between groups for each measurement showed that the original Portuguese sample displayed a larger magnitude of sexual dimorphism than the Taiwanese sample across all measurements, except for LBAS.

This project demonstrates that population specificity in sex estimation matters, even when dealing with the most sexually dimorphic element in the human body. These preliminary results further illustrate the need to incorporate diverse reference samples into forensic anthropological methods to ensure that forensic investigations are inclusive and precise for all populations.

A46 Adult Age Estimation From the Pubic Symphysis and Sternal Rib: A Combined Revision of the Hartnett Methods

Valerie Sgheiza, PhD, Honolulu, HI; Kristen Hartnett-McCann, PhD*, Connecticut Office of the Chief Medical Examiner, Farmington, CT*

Learning Objectives: After attending this presentation, attendees will gain a valuable tool for estimating adult age at death using combined data from the pubic symphysis and sternal end of the fourth rib. Attendees will have a better understanding of how a bivariate model in a Bayesian framework produces age estimates that are more biologically informed than classical or univariate regression: stage is regressed on age and traits are weighted in the model according to their informative values.

Impact Statement: This presentation will impact the forensic science community by providing easy-to-use and practical look-up tables for forensic anthropological adult age estimation combining the pubic symphysis and sternal end of the fourth rib. These tables will allow the forensic anthropologist to input age phases from both the pubic symphysis and sternal end of the fourth rib to obtain a model-based combined age interval incorporating both skeletal sites.

Abstract Text: Two of the most commonly used techniques for adult age estimation in forensic anthropology utilize the pubic symphysis on the pubic bone and the sternal end of the fourth rib. Methods for these skeletal elements most frequently rely on visual assessments of the topography and appearance of the joints, which demonstrate degenerative patterns corresponding to increasing age. Major criticisms of these age-phase methods center on sample composition, high inter- and intra-observer error rates, and the large age intervals of the phases established in the original studies. Furthermore, there are very few, if any, age estimation methods that combine visual assessments of the joints of both the pubic symphysis and sternal end of the fourth rib to produce a single statistically derived final age interval. This research produced simple and easy-to-use lookup tables that ultimately provide smaller age intervals than when the pubic symphysis and sternal end of the fourth rib are used individually.

The data in this research were extracted from the original dataset created by Hartnett.[1,2] The data are based on a sample of pubic bones and sternal fourth rib ends collected from decedents of known age, sex, and population affinity at the Maricopa County Forensic Science Center and Barrow Neurological Institute in Phoenix, AZ, in 2005 and 2006. The total collection (N = 630) consists of bilateral pubic bones and fourth rib ends from 419 males and 211 females, ranging in age from 18 to 99 years. Due to trauma, pathology, and preservation concerns, however, a total of 481 individuals with both pubic bones and rib ends were available for this statistical analysis.

Pubic symphysis and rib scores were modeled separately and together via univariate and bivariate cumulative probit, respectively, with age and sex as predictors. The residual correlation (trait correlation remaining after regression on age) between the traits in the bivariate model was 0.27; 95% highest density regions for age were estimated in a Bayesian framework with a uniform prior.

Ten-fold cross-validated performance metrics for the bivariate model were 92.8% accuracy, 0.26 mean ratio of age interval width to true age (precision), and Root Mean Square Error (RMSE) of 3.50 years. Although the sternal rib is more age-informative than the pubic symphysis, the bivariate model produced age estimates that were more precise (pubic symphysis: 0.77, sternal rib: 0.33) and had lower RMSE (pubic symphysis: 8.14, sternal rib: 7.32) than either univariate model. Bivariate accuracy was similar to univariate (pubic symphysis: 97.4%, sternal rib: 95.6%) and, more importantly, close to the expected value of 95% (Bayes Factor for proportion test against a 0.95 expected value: 1.4).

While the Hartnett methods see widespread use, there is currently no model-based means of combining score data from both methods. This presentation will provide a systematic means of combining scores into a single estimate while leaving the original scoring systems unchanged.

A47 Rethinking Expectations for Juvenile Growth and Development Based on an Analysis of a Michigan Medical Examiner Sample

Megan E. Carroll, BS, Northern Michigan University, Marquette, MI*

Learning Objectives: After attending this presentation, attendees will be more aware of how the World Health Organization (WHO) and Centers for Disease Control (CDC) published standards can be used when evaluating the skeletal growth and development of subadults.

Impact Statement: This presentation highlights how medicolegal professionals can evaluate whether or not subadults meet growth expectations by comparing anthropometric data collected during postmortem investigations with published data from the WHO and CDC. This presentation will impact the forensic science community by demonstrating how case-based data can facilitate early detection of atypical growth and development.

Abstract Text: When there is a high rate of subadults going through the Medical Examiner's Office (MEO), it is important to determine if there is a common underlying reason. The role of the MEO is to conduct forensic investigations, but also to assist with public health surveillance. Because these roles go hand-in-hand, the MEO often detects epidemics before any other public health entity. By evaluating a juvenile decedent's length (measured crown to heel) and weight at death and by comparing them to expected values, based on their sex and age as published by the WHO and CDC, it can provide insights into their lives.

This study involves the analysis of subadults (aged 0-19 years) from 602 cases that were investigated by Western Michigan University Homer Stryker M.D. School of Medicine, Department of Pathology (WMed) MEO, between 2014 and 2022. The objective of the study was to determine whether subadults whose deaths are investigated by a Michigan MEO exhibit growth patterns that are consistent with standards/expectations published by the WHO and CDC. Z-score values were used to indicate how far from the mean lengths and weight at their respective age the decedents were based on the data used to create the WHO and CDC growth charts. T-tests and Wilcoxon signed-rank tests were used based on the normality of the data to evaluate if there was a statistically significant difference between the medical examiner sample and expectations based on the published WHO and CDC growth charts. The mean weight-for-age z-scores of the subsets of age ranges divided into sex range from 2.663 (males 8-11 years old, $p=1.602\ e^{-4}$) to 4.195 (females 3-7 years old, $p=4.768e^{-7}$) indicating the weight of the decedents within the subsets are above what is expected based on the WHO and CDC growth charts. The mean length-for-age z-scores of the subsets of age ranges divided into sex range from -20.451 (females 3-7 years old, $p=9.537e^{-7}$) to 1.784 (females 0-2 years old, $p=1.589e^{-2}$) indicating the length of the decedents within some subsets are above the expected length, while some are below what is expected.

The results of this study indicate that the decedents examined at WMed deviate from growth expectations established by the WHO and CDC. While the variation may reflect secular change historically observed throughout populations, additional factors such as environmental stress and nutritional availability may also influence growth and development rates.

A48 Sex Estimation of the Patella Using Machine Learning in an African American Population

Eric Frauenhofer, MS, University of Dundee, Buffalo, NY*

Learning Objectives: After attending this presentation, attendees will understand the principles of machine learning, its applicability to forensic anthropology, and its reliability in estimating the sex of unidentified human remains from measurements of the patella.

Impact Statement: This presentation will impact the forensic science community by introducing a novel approach to estimating the sex of isolated patellae using machine learning. This method can be used reliably in various contexts, including individual sets of remains, commingled remains, and mass disasters.

Abstract Text: Forensic anthropologists routinely assist in the identification of unidentified human remains, often those that are skeletonized. This frequently involves the estimation of a biological profile, consisting of the sex, age-at-death, stature, and ancestry of the remains. Biological sex can be tremendously helpful in efficiently narrowing the pool of potential candidates, and it can also help more accurately estimate other aspects of the biological profile, such as age at death and stature. Traditionally, sex was estimated using observations of non-metric characteristics of the pelvis and skull. However, the 1993 *Daubert* ruling ushered in an era moving away from non-metric measurements to the development of metric methods backed by robust statistical frameworks for increasing the reliability and credibility of forensic anthropological techniques.

A method that combines robust statistics with computational programming, gaining popularity among forensic anthropologists, is machine learning, a type of artificial intelligence in which a computer learns patterns from known data to make predictions about unknown data. In forensic anthropology, machine learning can utilize data obtained from known individuals, such as those in documented skeletal collections, to train algorithms that aid in classifying unknowns, such as sex. Machine learning essentially teaches a computer to recognize known relationships and then use those patterns to make informed decisions about unknowns.

For this research, six measurements of the patellae of 200 African American individuals of known sex, age, and ancestry in the Hamann-Todd Osteological Collection at the Cleveland Museum of Natural History were subjected to machine learning. The patella was selected as it is a structurally sturdy element that is often found intact and therefore can be helpful for forensic investigation if other elements, such as the pelvis and skull, are unavailable for analysis. Orange Data Mining, a free software program for machine learning through the University of Ljubljana, Slovenia, assessed the measurements of 70% (140 individuals) of the sample to train logistic regression, random forest, K-Nearest Neighbors (KNN), and neural network supervised learning models that then estimated the sex of the remaining 30% (60 individuals) of the sample.

Classification accuracy for the tested sample ranged from 85.0% for the logistic regression and KNN models to 95.0% for the random forest model. The neural network model yielded a classification accuracy of 86.7%. The classification accuracies, especially that of the random forest model, suggest that machine learning can be used in forensic investigations to estimate the sex of unknown human skeletal remains with a high degree of reliability. Moreover, these classification accuracies are higher than the previously evaluated discriminant function analysis of patellar measurements for the same sample, which had a maximum accuracy of 83.5% for classifying sex.[1]

The research indicates that machine learning is a valuable and reliable technique for estimating sex from metric measurements of patellae. Research is currently underway to assess the utility of machine learning for estimating sex from patellar measurements in different ancestral groups, and whether machine learning of patellar measurements can reliably estimate other aspects of the biological profile, such as age at death and stature.

A49 Assessing the Effect of Method Options (Temporal Period, Ancestry, and World Region) on Sex Estimation Using MorphoPASSE v1.0

Laura Lovell, BSc, Colorado Mesa University, Lebanon, OR; Christiane I. Baigent, PhD, Colorado Mesa University, Grand Junction, CO*

Learning Objectives: After attending this presentation, attendees will better understand the effect of program-defined "method options" (ancestry, temporal period, and world region) on model accuracy when using MorphoPASSE v1.0 for biological sex estimation in human skeletal remains.

Impact Statement: This study will impact the forensic science community by evaluating the accuracy of MorphoPASSE across a range of potential forensic case scenarios and highlighting the importance of critically assessing case-specific contextual data to improve model accuracy and practitioner confidence.

Abstract Text: Determining the biological sex of skeletal remains is foundational to biological profile estimation.[1] Traditional methods for sex estimation rely on subjective trait assessment, making them: (1) sensitive to practitioner training and experience; (2) vulnerable to both intra- and inter-observer error; and (3) contradictory to the mission of the Anthropology Consensus Body (ACB) as the discipline works toward standardization within the framework of the Academy Standards Board (ASB).[1,2]

MorphoPASSE is an open-access program used in skeletal sex estimation.[1] The program removes subjectivity from sex estimation by integrating well-established cranial and pelvic traits with standardized trait definitions, scoring procedures, and schematic and specimen photos from which a trait score is derived. The program further allows the user to specify "method options," including temporal period, ancestry, and world region. Scores are assessed using the program's "on the fly" Random Forest Model, providing the analyst a case prediction probability of sex membership and model performance metrics.[1,3]

This study evaluated the effect of "method options" within a sample of 50 adult skeletons randomly sampled from the Colorado Mesa University Forensic Investigation Research Station (FIRS) curated osteological collection. Each skeleton was independently scored by the authors following MorphoPASSE protocol and assessed using the program's "on the fly" Random Forest Model using three configurations of "method options": (1) all "method options" unknown; (2) estimated ancestry only, derived from craniometrics assessed in FORDISC 3.1.322; and (3) all "method options" known based on self-reported donor biodemographic data.[1,4-6]

MorphoPASSE predicted biological sex with almost 100% accuracy in this study. Misclassification occurred in 6% of cases; in each case, sex was accurately classified in treatment 1, then misclassified in treatments 2&3. A non-parametric Friedman test detected a significant difference ($X^2 = 13.39$, $p = 0.001$) in accuracy across the three treatments. Post hoc pairwise comparisons using Wilcoxon signed-rank tests with Bonferroni correction ($\alpha = .05/3 = .017$) detected a significant difference between Test 1&2 ($Z = 87.0$, $p = .043$), but none between Test 1&3 ($Z = 100.0$, $p = .165$) or Test 2&3 ($Z = 187.5$, $p = 1.000$). Because attribution of sex is case specific, differences in donor specific accuracy statistics were assessed across treatments. Treatment 3 improved accuracy in 17% of cases, treatment 2 improved accuracy in 10% of cases; 19% of cases were unaffected (accuracy statistic 100% in all treatments). Accuracy was highest in treatment 3 (all 'method options' unknown), resulting in improved accuracy in 54% of cases.

Results suggest that practitioner education and experience are not barriers to effective use of MorphoPASSE when training is sufficient, and standardized trait definitions and scoring procedures are followed. While "method options" have the potential to enhance model accuracy, the inverse is also true and, in most scenarios, MorphoPASSE was most accurate when those data were excluded. Overall, it is recommended that "method options" be avoided or conservatively applied in forensic case context where these variables are likely to be estimates, though future study within a larger, more diverse sample is warranted.

A50 Digital Stature Estimation Using Radiographic Measurements of the Tibia

Atlantis Baron, MA, The University of Montana, Missoula, MT; Meradeth H. Snow, PhD, University of Montana, Missoula, MT*

Learning Objectives: After attending this presentation, attendees will understand how digital measurements can be used as an alternative to traditional osteometric tools for estimating human stature. This method offers a replicable approach for use in forensic identification and improving accessibility in forensic casework.

Impact Statement: This presentation contributes to the forensic science community by supporting the use of digital methods for stature estimation. It shows that digital techniques can be just as reliable as traditional ones, especially in cases involving culturally sensitive remains.

Abstract Text: This study evaluates the accuracy of stature estimation from tibial radiographs using digital measurement software compared to traditional regression formulas based on physical bone measurements. The hypothesis proposes that tibial lengths measured digitally can produce stature estimates with accuracy comparable to traditional osteometric methods.

A sample of 59 tibiae from the Forensic Anthropology Skeletal Trauma (FAST) database was analyzed. Maximum tibial lengths were measured from radiographic images and applied to three regression models: the widely used formula by Trotter and Gleser, a more recent model by Simon et al., and a new regression equation developed specifically for this dataset and digital method.[1,2] To assess accuracy, the study calculated correlation coefficients, mean and median errors, and the standard error of estimation. A one-way Analysis of Variance (ANOVA) was conducted, followed by Tukey's post hoc test to determine any statistically significant differences among the three formulas.

The results revealed that there was no significant difference in accuracy between the three regression models. The new formula performed comparably to both the Trotter and Gleser, and Simon et al. formulas.[1,2] These findings support the hypothesis that digital measurements can serve as a reliable, and replicable, alternative to traditional osteometric measurement methods when used for human stature estimation in forensic anthropology.

A51 Using Structural Equation Modeling to Investigate the Relationship Between Innominate Metrics and Morphology for Sex Estimation

Michael W. Kenyhercz, PhD, Phokus Analyica, Lakewood, OH; Kate M. Lesciotto, PhD, University of North Texas Health Science Center, Fort Worth, TX; Carter A. Unger, MA, The University of North Texas Health at Fort Worth, Fort Worth, TX*

Learning Objectives: The goal of this presentation is to examine the relationship between biological sex, innominate measurements, and innominate morphological traits. Attendees will learn how Structural Equation Modeling (SEM) can be utilized to investigate the contributions of continuous and ordinal data for estimating biological sex.

Impact Statement: This presentation impacts the forensic science community by demonstrating that innominate metrics and morphological trait scores provide independent information related to estimating sex. The presented data supports the need for forensic anthropologists to develop new methods capable of combining both data types.

Abstract Text: Existing methods for estimating biological sex rely on an assessment of gross morphological features or skeletal measurements; however, methods are typically limited to only one type of data, and the relationship between morphological and metric data is not well understood. SEM is a multivariate statistical technique that can be used to assess complex causal relationships between multiple observed variables (e.g., morphological trait scores or skeletal measurements) and between observed variables and latent variables (e.g., an underlying biological parameter, such as relative robusticity or sexual dimorphism, represented by several measurements grouped together).[1] The objective of this study was to utilize SEM to investigate whether morphological traits of the innominate and metrics of the innominate and hip provide independent information related to sex.

Data were collected from 145 individuals (62F; 83M) from three modern United States skeletal collections. Measurements were taken according to Fordisc 3.1, Data Collection Protocol 2.0 (DCP2.0), and *Diagnose Sexuelle Probabiliste* 2.0 (DSP2).[2-4] These metrics were also grouped into the following latent variables: FORDISC innominate (2 measurements), DCP2.0 innominate (11 measurements), DSP2 innominate (10 measurements), and functional hip (2 femoral and 2 innominate measurements). Three morphological traits of the innominate [ventral arc (VA), subpubic contour (SPC), and medial aspect of the ischiopubic ramus (MA)] were scored in accordance with MorphoPASSE.[5,6] SEM was used to examine the relationships between biological sex, innominate morphological traits, and innominate and femoral measurements. Sample sizes for each analysis varied, as individuals with missing data relevant to each of the relationships modeled by SEM were excluded.

As a preliminary step, SEM was used to confirm that known sex was a significant predictor of both the morphological trait scores and metrics. Sex significantly predicted all three innominate morphological traits ($p < 0.001$) with moderate-to-large effect sizes (VA: β=0.775, SPC: β= 0.703, MA: β= 0.455), with males exhibiting significantly higher scores than females for all traits. Sex was a significant predictor of most measurements, with the exception of three of the DCP2.0 and one of the DSP2 innominate measurements ($p > 0.050$).

Next, the relationships between the grouped metrics (representing latent variables) and morphological traits were examined. Metrics were not a significant predictor of the innominate morphological traits, with the exception of two groupings. FORDISC innominate significantly predicted male SPC scores (β= -0.025, $p = 0.028$) and DCP2.0 innominate significantly predicted female MA scores (β= -0.036, $p = 0.027$). Although significant, effect sizes were very small and only related to one of the three traits, suggesting the tested metrics do not strongly predict innominate morphological trait scores.

The results confirm that sex significantly predicts both innominate metric and morphological data individually, but these data provide independent information about sex. These findings highlight the importance of developing sex estimation models that can incorporate both metric and morphological trait data. The next phase of research will include an expanded set of postcranial metric data to investigate how population affinity might influence morphological innominate traits.

A52 Exploring the Relationship Between Heat-Related Fractures, Perimortem Context, and Trauma Mechanism

Allison Thomson, BS, University College London, Office of Naval Research, Naval Research Enterprise Internship Program, London, England, United Kingdom; Rylan Tegtmeyer Hawke, PhD, SNA International, Offutt AFB, NE; Catherine R. Jones, PhD, SNA International, LLC, Omaha, NE*

Learning Objectives: Through the presentation of this research, attendees will develop an understanding of the propagation of heat fractures in relation to existing trauma markers. Attendees will also learn methods to both quantitatively and qualitatively assess thermal trauma present on skeletal remains.

Impact Statement: This study will impact the forensic community by investigating the relationship between the propagation of heat fractures and perimortem trauma and elucidate the potential effects of trauma mechanism or trauma type on how this relationship interplays. Ultimately, this study seeks to provide preliminary data to expand the conversation in the forensic anthropology community as it pertains to thermal and perimortem trauma.

Abstract Text: This study explores how different perimortem circumstances (e.g., aircraft crash, tank explosion, landmine) and trauma mechanisms (sharp, blunt, projectile, blast, deceleration) may influence heat-related fractures. While thermal trauma and heat-related fractures are often examined within domestic or residential forensic contexts, this project aims to expand on previous research, developing methods, and assessing a potential relationship between skeletal thermal alteration and trauma mechanism.[1-7] To understand the extent and degree of thermal influence on the bone, the number of affected elements, severity of exposure, fracture types, and trauma interpretation were recorded via Excel and quantitatively analyzed for a potential relationship.

To test the assumption of an observable relationship between the extent of thermal alteration and the presence of perimortem trauma, 50 cases from the Defense POW/MIA Accounting Agency (DPAA), all with recorded instances of perimortem trauma and thermal alteration, were examined. Of the data collected, blast trauma presented in 10.8% of the total sample, blunt force in 44.6%, projectile in 21.5%, sharp force in 6.2%, and deceleration in 21.5%. Trauma was recorded as noted in the analyst's report, which allowed for each case to have multiple trauma mechanisms. When available, additional contextualizing information, noted in DPAA reports, could indicate a likely primary trauma mechanism (e.g., recorded cause of death). In terms of the interplay between thermal and perimortem trauma within this sample, heat-related fractures were present in one or more elements in 40% of cases (20 individuals). Long bones were most commonly affected (16/20), followed by flat bones (10/20), and short (2/20) and irregular (2/20) bones. Widespread thermal exposure generally saw greater fragmentation of elements and occurred more frequently in cases with an identified trauma mechanism consistent with deceleration and blast. Cases with projectile trauma identified as the primary trauma mechanism presented with fewer instances of thermal alteration, and, when present, such alteration was less extensive and affected a smaller portion of the assemblage.

Understanding and quantifying the distribution of heat-related fractures in relation to perimortem trauma supports the classification of thermal trauma in conflict-related investigations. Understanding trauma patterns can help further contextualize individuals within forensic and recovery settings, supporting identification processes. By expanding the current literature, which largely focuses on thermal trauma in civilian case work, and applying it to a wider context that includes conflict-related cases, this research supports the practice of forensic anthropology in humanitarian or military settings, where the multifaceted and often complex nature of trauma patterns differ from those seen in domestic circumstances.

A53 Assessing the Accuracy of Entrance and Exit Wound Characterization in Long Bone Gunshot Wounds

Alexandra Semma Tamayo, MSc, Binghamton University, Binghamton, NY; Tal Simmons, PhD, Virginia Commonwealth University, Jerusalem, Yerushalayim, Israel; Laure Spake, PhD, Binghamton University (SUNY), Binghamton, NY*

Learning Objectives: After attending this presentation, attendees will gain insights into the accuracy of long bone gunshot wound interpretation by practitioners, as well as the implications these findings hold for forensic casework.

Impact Statement: This presentation will significantly contribute to the forensic community by providing a comprehensive assessment of the accuracy associated with long bone gunshot wound interpretation. Additionally, it will highlight critical areas in gunshot wound analysis that need further consideration.

Abstract Text: Reconstructing projectile trajectories is critical in forensic investigations of gunshot trauma. Although only a few studies have examined the characteristics of gunshot wounds in long bones, significant variations in weapons, projectile characteristics, and velocities can lead to different fracture patterns.[1-3] This variability may impact the accuracy of interpreting gunshot wounds, particularly when distinguishing between entrance and exit wounds in long bones. This study aimed to explore the factors leading to correct identification of gunshot entrance and exit wounds amongst forensic practitioners.

An online survey was disseminated to forensic practitioners through forensic science associations (e.g. AAFS, ALAF), through social media, and by using snowball sampling (referral through colleagues). Eligible participants self-identified as having training and/or practical experience with analyzing human bone tissue. Participants completed a demographic section that included questions regarding participants' education, training, and years of experience in trauma interpretation.

The survey included photographs of faunal bones (pig humeri and deer metapodials) on which trauma had been experimentally inflicted using either a 9 mm non-expandible projectile fired from 5 meters or a .223 Remington from 20 meters. After the experiment, bones were macerated and reconstructed with dissolvable glue before being photographed. Images of five different gunshot wounds were presented to participants, who were asked to identify whether the wound was an entrance or an exit. Participants were also asked to rate their confidence levels in the interpretation provided, as well as the likelihood that they would include those interpretations in a forensic report.

A total of 48 participants from different backgrounds, between the ages of 18 and >60, responded to the survey. Generalized linear mixed-effects models were used to model the likelihood of correctly interpreting a defect as a function of the variables training, education, and experience.

Exit wounds were more frequently correctly identified (52%) than entrance wounds (38%). When presented with a tangential wound, participants seldom (2% of cases) selected "other" or "undetermined," and overwhelmingly identified them as either entrance or exit. Mixed effect models suggested that the primary predictor of correct identification was the type of wound (entrance/exit/tangential). Demographic variables, training, or education levels did not significantly account for differences in accuracy of interpretation (p-value ≥0.05). Interactions between years of experience and type of wound suggested that identification accuracy increases with experience for entrance wounds, but not for exit and tangential wounds; however, the interaction did not attain statistical significance.

Practitioners and academics showed a positive association between confidence and correctness, rating confidence more highly when they were, in fact, correct. Students, however, showed an inverse relationship; higher levels of confidence were associated with decreased accuracy.

These findings highlight the complexity of long bone gunshot wound interpretation, especially when differentiating defects in isolation. While participants with more experience tended to be more accurate and demonstrated better alignment between their confidence and correct interpretations, overall accuracy remained low. This highlights the need for improved and standardized characteristics that support defect interpretation for forensic practitioners at all levels of expertise.

A54 Asymmetry of Human Ribs: Considerations for Trauma Experiments and Interpretations

Randi M. Depp, PhD, Ashland University, Akron, OH*

Learning Objectives: This presentation will utilize clinical Computed Tomography (CT) scans of human decedents to challenge the basic assumption that human rib shape is symmetrical. After this presentation, attendees will understand different measures of 3D curvature and cross-sectional shape in human ribs, if these variables differ between right and left ribs, and that forensic anthropologists should consider rib side when experimentally testing rib biomechanics and assessing thoracic blunt force trauma.

Impact Statement: This presentation will impact the forensic science community by demonstrating key asymmetries of rib morphology that may affect rib biomechanical behavior. This is vital knowledge for researchers studying rib fracture mechanics and for forensic anthropologists interpreting thoracic blunt force trauma.

Abstract Text: Rib fractures are commonly encountered in cases of thoracic blunt force trauma from incidents like motor vehicle accidents and falls. However, fracture type, number, and location vary significantly among ribs regardless of loading scenario, and rib fractures are often difficult to predict or consistently replicate.[1-4] Both the complex 3D curvature of ribs and the cross-sectional geometric properties contribute to the biomechanical behavior of ribs. The effect of rib side is typically overlooked in rib fracture research, and asymmetries in rib shape may explain some of the variability in rib biomechanical behavior. This study utilized decedent CT scans to identify asymmetries in 3D curvature and cross-sectional geometry of ribs to inform future rib biomechanical experiments and fracture interpretations.

Clinical CT scans of 96 decedents were obtained from the New Mexico Decedent Image Database. Right and left ribs two through ten were segmented and surface meshes were generated. Centroidal paths of each rib were estimated and used to calculate the pitch angle, radius of curvature, and roll angle for each point along the curve. Cross-sections of the ribs were obtained by re-slicing the CT scans orthogonal to the rib surface and the total cross-sectional area, eccentricity, and theta angle were measured. Cortical thickness was estimated independently using a cortical bone mapping algorithm. All variables except total cross-sectional area and cortical thickness were significantly different between right and left sides for large portions of rib length. These results demonstrate that ribs are asymmetrical in 3D curvature and cross-sectional geometry, both of which are known to affect biomechanical behavior. Although no biomechanical testing was performed, future studies should consider rib side in their experimental design and reconsider using left and right ribs interchangeably.

A55 Bullet Wipe Analysis in Skeletal Gunshot Trauma Cases

Joe Adserias-Garriga, PhD, Mercyhurst University, Erie, PA; Flavia Rossell Hayes, BS, Mercyhurst University, Erie, PA; Chloe Yingling, BS, Mercyhurst University, Erie, PA; Sydney R. Carlson, APM, Mercyhurst University, Erie, PA*

Learning Objectives: Attendees to this presentation will acquire a better understanding of how residue presence changes according to Postmortem Interval Estimation (PMI) and the type of defect (entrance and exit).

Impact Statement: This presentation will impact the forensic science community by: (1) providing guidance on the radiographical technique used to evaluate the presence of bullet wipe in cases of gunshot trauma; (2) providing a deeper understanding of the presence of bullet wipe according to PMI estimation; and (3) reporting when bullet wipe was observed in exit defects.

Abstract Text: Bullet wipe refers to the halo of residue deposited by a bullet on any surface it contacts, such as skin, clothing, or bone after being fired. This residue primarily contains soot, but may also include particles of lubricant, powder by-products, metal fragments, and barrel debris, transferred as the projectile penetrates.[1] Such deposits may be visible radiographically as a radiodense bullet wipe, high-density particles around the gunshot defect, which helps to distinguish gunshot wounds from other trauma.[2,3] This residue forms due to friction as the bullet moves through tissues, wiping off coatings from the bullet's surface that accumulate in the wound perimeter, and it has been studied in entrance defects.[3]

Fifteen cases involving gunshot trauma were included in this study. The remains were radiographed with the Konica Minolta Regius Console CS-2 Version 1.30R00 Digital Imaging System, and detailed radiographs of the defects were taken with the Dexcowin Cocoon Portable Handheld Dental X-Ray System and Dentimax Dental Imaging Software. Case information recorded consisted of the decedent's biological profile, PMI, environment of deposition, if the defect corresponded to an entrance or an exit, and its location in the skeleton.

The results showed that both cranial and postcranial bones displayed radiographic evidence of bullet wipe. Cases showing radiographic signs of bullet wipe corresponded to a minimum PMI of 24 hours and a maximum of 4.8 years. Additionally, bullet wipe radiographic evidence was found in both entrance and exit defects.

The presence of radiographic bullet wipe evidence in entrance defects has been reported in previous studies using a similar radiographic technique as the one utilized in this project, showing a high efficiency in detecting the residue.[3-5] However, there is a lack in the scientific literature of evidence of radiographic bullet wipe in exit defects, which is described in this presentation.

The persistence of up to almost five years postmortem presents another novel contribution as most studies focus on autopsy specimens with very short PMI (generally hours to days).[6-8]

All these concepts will provide valuable information for future casework. This is a preliminary study that will be continued to understand the behavior of bullet wipe and allow for its proper interpretation.

A56 Sex-Specific Stature Estimation Using Upper and Lower Limb Anthropometric Measurements in the Modern South Indian Population: A Comparative Analysis of Regression and Mathematical Methods

Ambika Prasad Patra, MD, MBBS, FRCP, MBA, Jawaharlal Institute of Post-Graduate Medical Education & Research, Puducherry, Puducherry, India; Shashank Singh, MBBS, Junior Resident Department of Forensic Medicine and Toxicology. H.B.T Medical College and Dr. RN Cooper Hospital., Mumbai, Maharashtra, India*

Learning Objectives: The objectives of this presentation are to:

- Enhance forensic identification and compare methodologies. Evaluates and compares the predictive accuracy of Regression Analysis (RA) and Multiplication Factor (MF) methods for stature estimation from upper and lower limb measurements of the Modern South Indian population (MSI). This study introduces population-specific regression equations and multiplication factors for stature estimation in dismembered remains or mutilated cases.

- Population-specific approaches for stature estimation. This study underscores the importance of population-specific equations for stature estimation and introduces population-specific data in MSI.

- Sexual dimorphism in stature estimation. Highlights the influence of sexual dimorphism in stature estimation and the need for sex-specific anthropometric models to improve precision of stature estimation.

- Highlight limitations and adaptability. Acknowledging estimation variations and adaptability. Recognizes that Regression Equations (Res) and MFs may vary, recommending cautious application to other populations with specific adjustments.

Impact Statement: This presentation introduces validated regression equations and multiplication factors for estimating stature in the South Indian population, addressing a gap in forensic anthropology. It enhances identification accuracy for mutilated or dismembered remains in mass disasters and criminal cases. By comparing regression analysis with multiplication factors, the study provides recommendations for accurate stature estimation, with sex-specific results that improve assessments. High R^2 values and low standard errors confirm the robustness of the models, while Bland-Altman plots add statistical rigor. The presentation advocates for region- and sex-specific standards in forensic anthropometric analysis, ultimately promoting accurate and ethical identification outcomes.

Background: Forensic anthropology uses somatometry for identification, especially in dismembered or mutilated cases. While mathematical MF and RA methods are used for stature estimation, studies on the modern Indian population are limited. This study examines the Modern South Indian (MSI) population, which includes both native and migrated residents.

Aim: The objectives were to establish REs and MFs for estimating stature from upper and lower anthropometric measurements in the MSI population and evaluate their predictive accuracy against known stature.

Methods: This institutional, autopsy-based cross-sectional study includes 214 cases (117 males and 97 females) of hospital deaths from the MSI population. Data from Upper Limb (UL) and Lower Limb (LL) measurements—Arm Length (AL), Forearm Length (FAL), Palm Length (PL), Middle Finger Length (MFL), Thigh Length (TL), Leg Length (LL), Foot Length (FL), and Great Toe Length (GTL)—were used to estimate stature using linear Regression Analysis (RA) and mathematical Multiplication Factor (MF). The estimated stature's accuracy was assessed by comparing it with the known stature of deceased individuals, calculating Standard Errors of Estimate (SEE). A Bland-Altman (BA) plot compared the predictive accuracy of both methods.

Results: The study population's age ranged from 24–72 years in males and 22–68 years in females. Results showed significant correlations between UL and LL anthropometric measurements and stature. High R2 values and low SEE demonstrated reliable stature estimation. Sexual dimorphism was evident in UL and LL measurements. MFL had the strongest correlation with stature (R-0.866/males, SEE-0.14/males; R-0.91/females, SEE-0.10/females), while PL showed the weakest (R-0.778/males, SEE-0.32/males; R-0.865/females, SEE-0.24/females). FL and LL measurements showed predictive accuracy with coefficients of 0.865 (SEE-0.28) for males, 0.846 (SEE-0.29) for females in FL; and 0.846 (SEE-0.28) for males, 0.799 (SEE-0.31) for females in LL. Both methods overestimated male stature and underestimated female stature, with MF showing greater variability.

Conclusions: This study provides significant RE and MF for estimating stature from UL measurements in the MSI population, improving forensic identification. BA plot analysis showed the closest agreement between estimated and known stature measurements. While the MF method is simple, the RA method provides more precise estimates. These methods should be applied cautiously due to slight over- or underestimations and population-specific characteristics. Given high coefficients of determination and low estimation error, RA method findings provide a reliable framework for forensic investigations of mutilated or dismembered remains. This study emphasizes the need for sex-specific equations across populations.

Limitations: The developed REs and MFs can be adapted to other populations, albeit with necessary population-specific adjustments.

A57 Narrowing the Age Range: The Utility of Cranial Suture Methods in Aging

Lyndsey M. Hornagold, MS, Florida Insitute of Forensic Anthropology & Applied Science- University of South Florida, Lakewood Ranch, FL; Erin H. Kimmerle, PhD, Florida Insitute of Forensic Anthropology & Applied Science- University of South Florida, Tampa, FL*

Learning Objectives: The audience of this presentation will learn how age estimation using various cranial sutures applies to older adults. Also, participants will gain knowledge about the accuracy of this method to better understand the usefulness of age estimation with cranial sutures.

Impact Statement: This presentation will allow forensic anthropologists and other forensic scientists to make informed decisions regarding the methods they use for age estimation, especially for decedents who are older or in cases where only a skull or cranium is present for analysis.

Abstract Text: The degree of closure for various cranial sutures is used by forensic anthropologists to estimate the age of an individual. The sutures of the vault and lateral-anterior regions of the cranium are most commonly used.[1,2] The closure of the endocranial and palate sutures has also been studied as a potential method for age estimation.[1,3] However, these methods place older individuals into broad age categories, such as "older adult," which ages an individual as 50+.

The USF Donated Skeletal Collection housed at the Florida Institute of Forensic Anthropology & Applied Sciences at the University of South Florida was analyzed for this study. To test the accuracy and explore the potential expansion of the current cranial suture age categories, the vault, lateral-anterior, endocranial, and palate sutures were scored following the methods outlined by Meindl and Lovejoy and Buikstra and Ubelaker (1994): 0=open, 1=minimal closure, 2=significant closure, and 3=full closure or suture obliteration.[1,2] A total of 101 donors, 47 females and 54 males, aged 50 or older were scored. All donors self-identified on the antemortem information packet as either White or European ancestry. The age range of the sampled donors was 51 to 101 years of age.

Each donor had the following ectocranial, endocranial, palate suture or suture points scored: midlambdoid, lambda, obelion, anterior sagittal, bregma, midcoronal, pterion, sphenofrontal, inferior and superior sphenotemporal, incisive, anterior and posterior median palatine, transverse palatine, sagittal, left lambdoid, and left coronal. The scores from the selected sutures were added into composite scores for the vault, lateral-anterior, and endocranial, and palate regions. The vault composite scores range from 0 to 21, and the lateral-anterior scores range from 0 to 15. A composite score of 0 indicates the individual is a younger adult, while the maximum scores for both regions indicate the individual is an older adult, or 50+ years of age.[2] All composites between 0 and the maximum scores correlate to an age range as well as a mean age and standard deviation.[1,2] Composite scores for the endocranial and palate sutures have not been mathematically correlated to specific ages, except for the broad younger, middle, and older adult categories. A gooseneck flashlight was used to observe the endocranial sutures of donors without autopsy cuts.

The means, standard deviations, and ranges were calculated for the donor ages that corresponded to each composite score for both the vault and lateral-anterior sites. An Analysis of Variance (ANOVA) was performed and showed that there was no significant difference between the means of either the vault or lateral-anterior sites, indicating that the current method does not accurately age individuals over the age of 50. Using the interdecile range for each composite score, it was found that the vault sites accurately aged donors in about 17% of cases, while the lateral-anterior sites were found to be 28% accurate, with no significant differences when accounting for sex. Overall, more research into the cranial suture closures of older individuals is needed for this method to be utilized effectively.

A58 An Evaluation of Microscopic Techniques in Cementochronology for Forensic Age-at-Death Estimation

Amando L. Montalvo, Jr., MS, The University of Texas Rio Grande Valley, Mission, TX; Carina Marques, PhD, The University of Texas Rio Grande Valley, Edinburg, TX; Benoit Bertrand, PhD, University of Lille, France, Lille, Nord-Pas-de-Calais, France*

Learning Objectives: The attendees will gain insight into the comparative performance of different microscopy techniques in cementochronology, with a focus on how method selection influences the precision and accuracy of age-at-death estimation.

Impact Statement: The impact of this presentation will advance methodological standardization in forensic dental histology by highlighting the critical role of microscopy technique in optimizing age-at-death estimation.

Abstract Text: The increasing integration of histological methods in forensic anthropology has underscored the potential of dental cementum as a marker for age-at-death estimation. Cementum, a mineralized connective tissue covering the tooth root, exhibits a layered structure formed by annual deposits that can be visualized under microscopy. While cementochronology has been explored for its forensic and bioarcheological applications, the literature largely focuses on histological protocols and debates concerning the reliability of age-at-death estimation, often overlooking the influence of different microscopic techniques on count performance.

This study aims to evaluate the reliability, precision, and accuracy of cementochronology across three microscopy techniques: brightfield (BF), differential interference contrast (DIC), and phase contrast (PC). It is hypothesized that PC, given its reported efficacy in previous studies, will yield the best repeatability, most consistent annuli count, and the highest accuracy in age-at-death estimation.

The study used a total of 40 canine teeth from the 21st Century Identified Skeletal Collection, Portugal. This cohort includes 62.5% males (n = 25) and 37.5% females (n = 15), with a mean age-at-death of 64.8 years (SD =19.1 years, median= 68.5 years, range = 25-92 years), who died between the years of 1997-2008. Intra-observer error was assessed using the initial three annuli counts as a subset of eight counts. Precision was assessed by evaluating the agreement between eight cementum counts. Accuracy was determined by comparing the estimated age-at-death with the known chronological age. This study utilized a standardized histological preparation protocol.[1]

The three microscopy techniques diverged in their performance when comparing the rTEM (Relative Technical Error Measurement) of the initial three annuli counts per technique. The results showed that PC and DIC (rTEM = 10.4%) had the same repeatability, whereas BF had a lower repeatability (rTEM = 11.5%). Furthermore, assessments of precision based on standard deviation (SD) as a measure of absolute precision and coefficient of variation (CV) as a measure of relative precision, support the higher precision of PC (SD = 6.0 annuli, CV = 14.0%) when compared with DIC (SD = 7.0 annuli, CV = 16.0%) and BF (SD = 8.8 annuli, CV = 23.0%). When comparing estimated vs. actual age-at-death, PC demonstrated higher accuracy. The relative error of PC (Δ% age = 24.0%) was better than that observed for DIC (Δ% age= 26.0%) and BF (Δ% age = 28.0%).

Phase contrast exhibited the best reliability, highest precision, and best accuracy. However, all three techniques yielded significantly poorer results in comparison to other works. The predominance of older individuals in the current sample may have influenced this outcome. These findings underscore the relevance of PC as a reliable method for consistent annuli counting, while also suggesting that future studies incorporating a broader age distribution, particularly a greater proportion of younger individuals, may offer complementary insights into the relationship between sample characteristics, intra-observer error, precision, and accuracy in cementochronology.

A59 Anterior Mandibular Morphometry and Its Application in Juvenile Biological Profiling: A Quantitative Analysis and Possible Implications

Jennifer Geisen, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Satu Valoriani, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will be able to better understand the potentials of applying morphometric measurements of the mandibular anterior region—specifically intercanine and interincisal widths and mentum height—for estimating age in juvenile skeletal remains and critically assess their limitations in determining sex.

Impact Statement: This presentation will impact the forensic science community by enhancing practitioners' competence in juvenile age estimation through the use of mandibular morphometric analysis, improving their ability to apply alternative osteometric techniques in cases involving incomplete or fragmented remains, and ultimately strengthening the accuracy and reliability of biological profiling in subadult forensic cases.

Abstract Text: Morphological sex and age assessment in juveniles remains one of the most persistent challenges in forensic anthropology. While the estimation of age using dental development and eruption patterns is widely regarded as reliable, it is heavily dependent on the presence of a complete or near-complete dentition—an assumption that may not hold in many forensic contexts, particularly in fragmented or degraded remains.[1-3] Similarly, traditional approaches to juvenile sex determination have relied on sexually dimorphic features of the ilium and cranial morphology; however, these traits tend to be subtle or underdeveloped in children, especially prior to puberty, thereby limiting their practical application.[4,5]

To address these limitations, the authors explore the potential of a morphometric evaluation of the mandibular anterior region for biological profiling. The research's goal is to assess whether this anatomical region, which is often preserved even in fragmented remains and have been tested for adults in some populations, could serve as reliable osteometric marker in juvenile identification.[6]

The study analyzed Computed Tomography (CT) scans from 340 individuals (206 male, 134 female), aged 1 to 16 years from the New Mexico Decedent Image Database.[7] Individuals aged between 6 to 8 years old have been excluded due to mixed dentition, which could jeopardize measurement consistency. Linear measurements were taken from the lateral borders of the left and right mandibular central incisors, lateral incisors, and canines. Additionally, mentum height—from the alveolar crest between the central incisors to the inferior margin of the mandibular symphysis—was recorded. These variables were statistically analyzed to evaluate their predictive value for both age and sex, using independent samples t-tests, one-way Analysis of Variance (ANOVA), and regression modeling.

The results indicate that there is no statistically significant relationship between the examined mandibular measurements and the sex of the individuals. However, a strong and statistically significant relationship was found between age and the combined measurements of the lateral incisors, canines, and mentum height ($F(3,258) = 424.305$, $p < .001$). The regression model yielded an R^2 of .831 (adjusted $R^2 = .830$), suggesting a high degree of predictive accuracy for age estimation using these parameters.

In conclusion, while these mandibular features do not appear to offer forensic utility for juvenile sex determination, they demonstrate considerable potential for age estimation, particularly in cases where only partial mandibular remains are recovered. These findings contribute to expanding the repertoire of age estimation methods in subadult forensic cases and underscore the utility of the mental region as a valuable alternative when conventional indicators are absent or compromised.

A60 Investigating the Correlation Between Body Mass and Hip Joint Measurements in a Taiwanese Non-Adult Sample

Rachel Riddell, BA, George Mason University, Vienna, VA; An-Di Yim, PhD, George Mason University, Manassas, VA*

Learning Objectives: After attending this presentation, attendees will learn how hip joint morphology can be used to estimate body mass in non-adult skeletal remains, specifically in the Taiwanese population. This presentation will provide an insight into the applicability and limitations of current methods of body mass estimations involving the hip joint as well as emphasize the need for population- and age-specific standards for these measurements in the field of forensic anthropology. Additionally, this research will highlight the importance of diverse skeletal samples in methodological development to further inform and improve accuracy in forensic identification.

Impact Statement: This research will impact the forensic science community by providing a better understanding of the applicability and limitations of current methods of body mass estimations involving the hip joint and highlighting the importance of diverse skeletal samples in methodological development to further inform accuracy in forensic identification.

Abstract Text: Previous studies have examined the effect of mechanical stimuli on bone morphology with relation to weight-bearing structures of the hip. Notably, a recent study out of Texas State University has examined this relationship in adults, analyzing how variations in Body Mass Index (BMI) correspond to macroscopic differences of the femur, with additional attention to patterns of sexual dimorphism. While these studies have made progress to incorporate measurements of the lower limbs to inform an adult BMI score, the application of this methodology to the non-adult skeleton remains has not been extensively studied. This gap in the current literature is critical, as an accurate estimation of body mass in juvenile remains can be essential for forensic identification, especially in cases involving unidentified or fragmented non-adult remains. This study investigated the correlation between body mass and specific measurements of the hip joint (the maximum articular breadth, or diameter, of the femoral head) in a Taiwanese non-adult sample, addressing a significant gap in forensic anthropology and forensic science.

This study used 85 Computed Tomography (CT) scans of individuals assigned male and female at birth between 1 and 15 years old from National Taiwan University Hospital. Three-Dimensional (3D) models of proximal femurs were created and aligned using 3D Slicer. The sample was divided into separate weight categories based on the BMI: normal (< 95th percentile) and obese (≥ 95th percentile), and Multivariate Procrustes analysis was used to compare the shape of the proximal femur across body mass and age categories to explore a potential correlation. Additionally, a relationship has been established in previous literature between the maximum articular breadth (or diameter) measurement of the femoral head to body mass in subadults, and these measurements were applied to the Taiwanese non-adult sample.

The findings indicated there is a slight difference between normal weight and obese non-adult individuals, starting around puberty (age 12 for males and age 11 for females) in the Taiwanese sample. There is a clear positive correlation between body mass and femoral size, but no correlation between body mass and shape deformation. These results correspond with previous studies on adult femoral size change as it relates to obesity, providing valuable insight into the effects of childhood obesity on bone morphology—especially while the bone is still developing—as well as contribute toward a greater accuracy in forensic investigations involving juvenile skeletal remains.

A61 Stature Estimation Based on Femoral Dimensions: A CT Study on Contemporary Greeks

Despoina E. Flouri, MD, Forensic Medicine Unit, School of Medicine, University of Crete, Iraklion, Crete, Iraklion, Greece; Maria Arkouli, Biology Department, University of Crete, Iraklion, Crete, Iraklion, Greece; Elena E. Kranioti, PhD, Forensic Medicine Unit, School of Medicine, University of Crete, Iraklion, Crete, Iraklion, Greece; Antonios Papadomanolakis, PhD, Forensic Pathology Division of Crete, Hellenic Republic, Ministry of Justice, Transparency and Human Rights, Iraklion, Crete, Iraklion, Greece; Efsevia Daskalaki, MSc, Forensic Medicine Unit, University of Crete, Iraklion, Crete, Iraklion, Greece; Eirini Chasapi, MSc, Forensic Medicine Unit, University of Crete, Iraklion, Crete, Iraklion, Greece*

Learning Objectives: After attending this presentation, attendees are expected to understand the importance of population-specific standards in biological profiling, focusing on stature estimation. Additionally, a feasible, user-friendly approach at data acquisition using Postmortem Computed Tomography (PMCT) scans will be explained and proposed.

Impact Statement: This presentation will impact the forensic science community by proposing data acquisition frameworks using imaging modalities for purposes of biological profiling, focusing on stature estimation. The present work serves as a demonstration for the effect of population affinity in the accuracy of produced estimates by testing a preexisting population–independent method and proposing a population–specific method for contemporary Greeks.

Abstract Text: Stature constitutes one of four pillars of biological profiling and as such it has been extensively studied by the forensic anthropology community. In 2016, Albanese et al. proposed a population-independent approach for stature estimation employing linear measurements of the long bones, including the femur.[1] In the present study, a mixed population is used to test the validity of the proposed method. Additionally, a set of population-specific formulae for stature estimation is proposed for the Greek population using femoral measurements acquired through PMCT scans.

A total of 138 PMCT scans acquired at the Forensic Medicine Unit of the University of Crete, Greece, were retrospectively collected. The sample consisted of 55 adult females and 83 adult males of known age and ethnicity. Stature was measured during autopsy and recorded in the official case files. Right and left femoral bones were segmented using the open-source software 3D Slicer v. 5.8.0 and three linear measurements were collected: Maximum Length (L), Vertical Head Diameter (VHD), and Maximum Distal Breadth (DB). L measurements were used to test the Albanese et al. method for the pooled sample (N = 138).[1] The Greek sample (N = 112) was subsequently used to develop univariate and multivariate linear regression formulae for stature estimation. Leave-One-Out cross validation was performed, and model performance metrics were calculated using the open-source software Orange.

When applying the Albanese formula for the femur, in 38–58% of the cases, real stature was not included in the predicted range. For those instances, the difference between actual and predicted stature ranged between 7–27 cm, with the method displaying significant tendencies for stature underestimation. For the Greek population regression formulae, best performance was achieved when both L and DB were employed in all cases. As a single variable, L appeared to be most significant, whereas VHD appeared to negatively affect all models. Overall, model performance achieved R2 up to 0.72 and MAE ranging between 4-6 cm.

On the premises of the present work, it becomes evident that the Albanese et al. method cannot be safely used for the Greek population, and, therefore, its applicability on other populations may need to be reconsidered as well.[1] At the same time, the importance of developing population-specific standards is highlighted to optimally serve each forensic framework and to avoid gross miscalculations that could potentially hinder positive identification of unknown remains.

A62 Tiny Proteins, Big Impact: Rethinking Sex Estimation Through Dental Proteomics

Niharika Bhardwaj, MSc, Panjab University, Chandigarh, Chandigarh, India; Shubham Thakur, MSc, Panjab University, Chandigarh, Chandigarh, India; Sanya Gaur, PhD, Panjab University, Chandigarh, Chandigarh, India*

Learning Objectives: This presentation aims to inform attendees about the emerging role of dental proteomics in forensic sex estimation with a focus on the use of amelogenin peptides.

Impact Statement: This presentation will impact the forensic science community by helping the attendees to gain a better understanding on using proteomics as a sex estimation tool, including its methodological advancements and current limitations.

Abstract Text: Forensic anthropology has witnessed a revolution in the past decade and driving this change is a molecular approach we now know as enamel proteomics. Yet when we try to solve the questions of identity, tooth enamel is not usually the first thing we think of. But when skeletal remains are incomplete, sex estimation can feel like an educated guesswork. This is precisely where dental proteomics enters with a solution.

This review brings together the past decade of studies on proteomic sex estimation utilizing amelogenin peptides from human enamel. The studies were examined to extract comparative understandings into sample type, extraction protocols, and instrumentation. Among the reviewed extraction protocols, acid etching emerged as a technique that particularly stands out due to its minimally invasive nature. Core instrumentation remained largely consistent, but variability in equipment models impacted peptide detection. A few studies employed Liquid Chromatography/Mass Spectrometry (LC/MS) in Data Dependent Acquisition (DDA) mode for broad peptide detection while others combined both DDA and Parallel Reaction Monitoring (PRM).[1-5] PRM is a targeted technique used within high resolution LC/MS systems. One specific study by Koenig et al. talks about how this approach helped them to create a proteomic workflow that is highly throughput and allowed them to process approximately 200 samples per day, making it nearly ten times faster than traditional DNA-based methods for determining sex.[5] This impressive speed not only shows how scalable proteomics is, but also points its potential for routine use in large scale forensic investigations.

The review does not just focus on the successes. It also discusses some key challenges such as peptide degradation and the rare risk of Amelogenin Y (AMELY) deletions. This issue is examined in detail by Štamfelj in a focus article that highlights the diagnostic risk of mistakenly identifying males as females due to AMELY deletions.[6] By bringing together evidence from multiple studies, this review concludes that while the innovation is exciting, there are also some changes to be made in order to refine these methods and question their limits. Proteomics is not the answer for everything, but it remains one of the most promising directions we can pursue in forensic anthropology.

A63 Using Virtual 3D Models of the Pelvis to Explore Biometric Relationships Between Transgender and Cisgender Adults

Taylor M. Flaherty, PhD, University of Nevada, Las Vegas, Detroit, MI; Molly Morano, University of Nevada, Las Vegas, Las Vegas, NV; Jennifer F. Byrnes, PhD, University of Nevada, Las Vegas, Las Vegas, NV; Carl Streed, MD, Boston University, Boston, MA; Amy Weimer, MD, University of California, Los Angeles, Santa Monica, CA; Mark S. Litwin, MD, University of California, Los Angeles, Los Angeles, CA*

Learning Objectives: Attendees will learn about the quantifiable relationship between pelvic biometrics collected from Transgender and Gender-Diverse (TGD) (trans) adults using Gender-Affirming Hormone Therapy (GAHT) and cisgender comparators. Conclusions will help the forensic anthropology community better understand contemporary relationships between sex, gender, and skeletal morphology and how these may impact assessments of skeletal sex. Recommendations for best practices moving forward will be discussed.

Impact Statement: This presentation will enhance forensic anthropologists' competency by offering early insight into the influences of GAHT on skeletal morphology. By integrating these findings, forensic anthropologists can improve their ability to identify and represent trans decedents accurately. This contributes to more equitable outcomes in medicolegal casework by reducing misclassification, enhancing case resolution, and supporting forensic practices that promote justice for all decedents.

Abstract Text: The human body is influenced by numerous hormones, including reproductive hormones such as estrogens, androgens (e.g., testosterone), and progesterone. While humans naturally produce these hormones in varying concentrations, GAHT can modify their levels to align with a person's gender identity. Trans people often use GAHT to support phenotypic gender expression, which gradually changes with GAHT treatment. Skeletal responses to GAHT remain widely under-researched despite the essential role of reproductive hormones in bone health and metabolism. Moreover, forensic anthropology methods for estimating skeletal sex may produce results that do not align with people's lived experiences, potentially impeding the resolution of unidentified and missing persons cases.

In partnership with the GenderCare Center at Boston Medical Center and the University of California, Los Angeles Gender Health Program, this study used Computer Tomography (CT) scans from trans adults using GAHT to produce stereolithic pelvis models. Twelve measurements adapted from previous research were collected from all samples and compared to measurements collected from age-matched cisgender adults using the New Mexico Decedent Image Database.[1,2] Interlandmark distances and subpubic angles were adapted from Boogers et al. and Sitek et al. to measure gross pelvic measurements.[1,2] Researchers hypothesized that those using GAHT would more closely resemble their gender group rather than their assigned sex at birth due to skeletal plasticity and the known effects of GAHT on skeletal and soft tissues.

Initial findings were from a pilot assessment using 30 samples, indicating that at least one-third of the measurements were not significantly different between trans and cisgender groups; considerable overlap was also observed in nearly all samples, with no measurements resulting in identifiable, mutually exclusive groups. The intersection of ranges suggested that trans adults using GAHT for at least one year and cisgender adults with no history of GAHT treatment may have similar pelvic measurements, resulting in skeletal sex estimates that are incongruent with sex and gender identities used during life. Findings presented at AAFS will include approximately 150 pelvic samples of TGD patients and age-matched cisgender males and females to observe if the preliminary findings hold with a larger sample. Results contribute to the growing body of literature showing mixed effects of GAHT on the skeleton, which may be unique to the individual. This study highlights the potential compounding effects of internal and exogenous pressures on the human skeleton and how these may impact forensic investigations.

A64 Testing Posterior Probability Informed Thresholds Using the Innominate, Cranial, and Combined Traits in MorphoPASSE: Best Practice Recommendations

Kate M. Lesciotto, PhD, University of North Texas Health Science Center, Fort Worth, TX; Alexandra R. Klales, PhD, Washburn University, Topeka, Ks*

Learning Objectives: The goal of this presentation is to inform attendees about sex estimation accuracy rates using either the innominate traits, the cranial traits, or a combined set of traits when using MorphoPASSE. Additionally, Posterior Probability Informed Thresholds (PPITs) are developed for each set of traits.

Impact Statement: This presentation will impact the forensic science community by providing best practice recommendations for using MorphoPASSE. These recommendations will also help standardize how sex estimation results are reported in forensic case reports.

Abstract Text: Skeletal sex estimation plays a crucial role in early investigations to narrow down the potential decedent pool. Forensic anthropology practitioners use a wide variety of sex estimation methods, including methods that utilize osteometric and morphological data. When using morphological traits for sex estimation, the innominate and skull are considered the most informative skeletal elements. MorphoPASSE is a commonly used program that allows users to estimate sex based on morphological traits of either the innominate or cranium, or a combined set of traits; however, MorphoPASSE does not provide recommendations on which set of traits performs best or recommend a PP threshold for sex classification in modern forensic casework.[1]

The goals of this study were to compare accuracy rates when using different sets of traits in MorphoPASSE, test whether PPITs can significantly improve sex estimation accuracy, and provide best practice recommendations. Innominate and cranial traits were scored based on the descriptions and figures in the MorphoPASSE user manual, and data were collected from four modern United States-documented skeletal collections (n = 285).[2] Sex was estimated in the MorphoPASSE Graphical User Interface (GUI) using the random forest model, with the following parameters selected to mimic United States casework: contemporary temporal period, United States region, and unknown ancestry. For each individual, sex was estimated through three model runs: using only the three innominate traits, using only the four cranial traits, and using the full set of all seven traits. Five mutually exclusive PP intervals were examined (0.50-0.649, 0.65-0.749, 0.75-0.849, 0.85-0.949, and 0.95-1.00), and accuracy rates were calculated for each separate PP interval. Binomial tests were used to examine whether the accuracy rate (proportion of correct predictions) of each PP interval was significantly different from random chance. The PP intervals that did have accuracy rates that were significantly different from random chance were further explored to develop PPITs for classification.

The 0.85-0.949 and 0.95-1.00 PP intervals had significantly higher accuracy rates compared to chance for both the innominate traits and cranial traits (all $p < 0.005$). These intervals were condensed into a 0.85-1.00 PPIT and produced higher accuracy rates for both the innominate (97.3%) and cranial (90.9%) traits. The 0.75-0.849, 0.85-0.949, and 0.95-1.00 PP intervals had significantly higher accuracy rates compared to chance for the combined set of traits (all $p < 0.005$). Using a 0.75-1.00 PPIT, the combined set of traits resulted in an accuracy rate of 99.6%, demonstrating that higher accuracy rates are possible when using both innominate and cranial traits with a lower PPIT for sex classification. Therefore, when both elements are available for analysis, the combined set of traits should be used. Individuals with a PP falling within the recommended PPIT should be reported as consistent with the male or female reference samples, while those falling below should be reported as "could not be estimated." Statistical results do not support the use of a "probable" qualifier for sex estimation. Use of these recommendations will help standardize the use of MorphoPASSE and reporting sex estimation results.

A65 A New, Flexible, and Accurate Method for Histological Age Estimation From the Femoral Midshaft

Timothy P. Gocha, PhD, Oklahoma Office of the Chief Medical Examiner, Tulsa, OK; Shelby Garza, PhD, Sam Houston State University, Huntsville, TX; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH; Michael W. Kenyhercz, PhD, Phokus Analyica, Lakewood, OH; Justin Z. Goldstein, PhD, NYC Office of Chief Medical Examiner, New York City, NY; Tessa M. Herbert, MA, Department of Anthropology at Texas State University, Austin, TX*

Learning Objectives: After attending this presentation, attendees will understand spatial variation of intracortical remodeling events (a.k.a. osteons) in the anterior femoral midshaft. Additionally, attendees will learn how this informs a newly developed, flexible method for histological age estimation from the femur.

Impact Statement: This presentation will impact the forensic science community by introducing a new, flexible method for histological age estimation from the femur, further demonstrating the method to be highly accurate throughout the adult life span.

Abstract Text: As a complement to macroscopic aging methods, or when necessary macroscopic elements are damaged/absent, age can be estimated through histological examination of remodeling events in cortical bone. For more than half century, the femoral midshaft has been the most examined anatomical site for histological age-estimation studies. However, previous methods used various Regions Of Interest (ROIs) differing in size, number, and location within the cortex, begging the question—where does remodeling best track chronological age? Previous research using Geographic Information Systems (GIS) to spatially analyze all remodeling events across the entire femoral midshaft in 30 individuals demonstrated significant spatial variation in remodeling but that the anterolateral, anterior, and anteromedial octants tend to best track age[1].

Building upon that finding, this research utilized femoral midshafts from seven modern histological/skeletal collections. The sample consists of 183 femoral cross-sections (95 males, 88 females), ranging from 15–107 years old (median = 52 years), with more diversity in population affinity than previous histological methods. Cross-sectional images were imported into ArcGIS Pro for data collection, within which polygon features were used to divide the cortex circumferentially into octants and radially into periosteal, intracortical, and endosteal thirds. All osteons within the anterolateral, anterior, and anteromedial octants were digitally mapped using point features, differentiating between intact and fragmentary osteon morphotypes. Three different sampling strategies were then applied: (1) all three octants, (2) the anterior octant, and (3) a fixed 10mm-wide anterior ROI spanning the periosteal to endosteal borders. Osteon Population Density (OPD) was calculated, as well as intact OPD (iOPD) and fragmentary OPD (fOPD). Biological sex was found to have no significant impact on remodeling data, so males and females were combined for analyses. In total, 524,803 remodeling events were quantified across nearly 29,000 mm^2 of cortical bone analyzed, eclipsing the amount of bone analyzed in previous histological research by nearly tenfold.

Random forest regression modeling was used for statistical analyses in R (4.5.0), and each model underwent parameter tuning to yield the most realistic and reproducible results individually. All forests employed sampling without replacement, ten random split points per candidate variable, and mean-squared-error splitting. Highest accuracy was achieved by the three-octant composite method ($R^2 = 0.722$; median absolute error = 3.7 years), followed by the anterior octant method ($R^2 = 0.680$; median absolute error = 6.0 years), and then the fixed 10-mm method ($R^2 = 0.645$; median absolute error = 5.8 years).

A free web-based Graphical User Interface (GUI) has been developed that allows practitioners to easily convert collected data to an age estimation, eliminating the need for complicated calculations.[2] The GUI permits the user to select which of the three sampling strategies they used and can accommodate counts of both intact and fragmentary osteons to have these analyzed separately or simply input the total number of remodeling events if the user chose not to differentiate osteon morphotypes. As such, this research offers practitioners a new, highly accurate, and more flexible method for age estimation via histological analysis than previously available.

A66 Age-at-Death Estimation Using Micro-CT Analysis of the Hyoid Bone: A Forensic Anthropology Approach

Samuele Baldi, MD, Department of Legal Medicine and Forensic Sciences, University of Pavia, Italy, Trecate, Piemonte, Italy; Giovanni Cecchetto, MD, PhD, Department of Legal Medicine and Forensic Sciences, University of Pavia, Italy, Pavia, Lombardia, Italy; Gulnaz T.Javan, PhD, Alabama State University, Montgomery, AL; Chiara Giraudo, MD, PhD, University of Padova, Padova, Veneto, Italy; Miriam Nomba Belem, University of Pavia, Pavia, Lombardia, Italy; Laura Secco, MD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy*

Learning Objectives: By attending this presentation, participants will learn how histomorphometric analysis of the hyoid bone using micro-Computed Tomography
(μ-CT) imaging can contribute to estimating the biological age of unidentified deceased individuals. This study will provide attendees with an innovative and consistent forensic anthropology tool for age-at-death estimation.

Impact Statement: This presentation will impact the forensic science community by demonstrating the validity of a novel analytical approach applied for the first time to the hyoid bone. The study offers an advancement in age estimation methods, enhancing competence in skeletal analysis and performance in postmortem identification, with potential relevance for medicolegal investigations.

Abstract Text: Recent years have seen the implementation of new methodologies aimed at improving age estimation in forensic anthropology.[1,2] Among them, micro-CT (μ-CT) analysis of trabecular bone microarchitecture has emerged as a promising technique to quantify age-related structural changes.[3] Histomorphometric analysis of bone tissue was first proposed in forensic anthropology by Stout and Paine in the 1990s, but has only recently gained traction.[4,5] This study applies these principles to the hyoid bone, an anatomical structure rarely affected by mechanical stress and, therefore, potentially more reliable for morphometric age estimation.

While the hyoid has been used in forensic studies with other techniques such as X-ray and 3D-CT, no prior research has applied μ-CT to assess its trabecular architecture.[6,7] The objective of this study was to examine the trabecular structure of the hyoid body and greater horn using high-resolution μ-CT in order to identify age-related changes. The hyoid bones were collected during routine medicolegal autopsies from male individuals of known age, divided into three age groups (≤40 years: N = 8, mean = 29.5 years; 41–60 years: N=8, mean=52.6 years; >60 years: N = 9, mean = 77.2 years), and subsequently subjected to μ-CT analysis. The resulting 3D datasets were analyzed using CTAn (CT-Analyser) software, assessing key parameters such as Bone Mineral Density (BMD), Bone Volume Fraction (BV/TV), Bone Surface Density (BS/BV), Trabecular Thickness (Tb.Th), Trabecular Separation (Tb.Sp), Connectivity (Conn), and Degree of Anisotropy (DA). The results show statistically significant differences across the three defined age-at-death groups for both the hyoid body and greater horn. In particular, the mean values revealed a consistent decrease in BMD, BV/TV, Tb.Th and Conn, as well as an increase in Tb.Sp with advancing age.

These findings confirm the potential of this method for biological age assessment, underline the utility of μ-CT as a powerful diagnostic tool for age estimation, and introduce the microtomographic analysis of a previously unexplored skeletal region in this context. Moreover, the hyoid bone represents a small and easily retrievable anatomical structure, making it particularly suitable for forensic applications. This study, therefore, offers an innovative and practical contribution to forensic science, with direct implications for routine forensic casework and postmortem identification.

A67 A Micro-CT Evaluation of the Sternoclavicular Joint for Age-At-Death Estimation: A Quantitative Microstructural Analysis

Laura Secco, MD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Pasquale Padalino, MD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Chiara Giraudo, MD, PhD, University of Padova, Padova, Veneto, Italy; Guido Viel, MD, PhD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Stefano Palumbi, MD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Giovanni Cecchetto, MD, PhD, University of Pavia, Department of Public Health, Experimental and Forensic Medicine, Padova, Veneto, Italy*

Learning Objectives: After attending this presentation, attendees will learn how micro-Computed Tomography (micro-CT) can quantitatively assess age-related trabecular and cortical microstructural changes affecting the sternoclavicular joint for adult age-at-death estimation. The presentation will demonstrate the discriminatory power of specific bone parameters across different age groups and sexes, highlighting sex- and site-specific bone remodeling patterns and exploring potential biological mechanisms behind these differences. Participants will also understand how integrating micro-CT quantitative microstructural analysis with qualitative morphological assessment of the sternoclavicular joint can enhance the objectivity and reliability of forensic age-at-death estimation.

Impact Statement: This presentation will enhance the forensic science community's competence in adult age-at-death estimation by introducing a reliable and objective micro-CT-based method focused on quantitative microstructural assessment of the sternoclavicular joint. Given the limited number of validated methods currently available for age-at-death estimation in adults, this research addresses a critical gap by providing objective and reproducible parameters with proven discriminatory power across different age groups, thus improving the accuracy and reliability of forensic assessments. These findings support more robust age-at-death estimations, ultimately strengthening stakeholder confidence in forensic identifications within legal and medicolegal contexts.

Abstract Text: The sternoclavicular joint plays an important role for age-at-death estimation in forensic anthropology, particularly through the assessment of the Medial Clavicular Ossification (MCO) stage, which, however, is applicable only to subadults and young individuals under 30 years of age.[1] For older individuals, alternative approaches have been proposed in recent decades, including macroscopic assessment of morphological degenerative alterations affecting the clavicle's medial articular surface and the histomorphometric or microtomographic analysis of clavicular trabecular bone.[2-4] However, no study has specifically investigated the sternal extremity of the sternoclavicular joint. This study builds on previous research that employed micro-CT to analyze morphological degenerative changes on the external surface of the sternoclavicular joint according to a modified "Falys-Prangle method," showing a positive correlation with age.[5] However, given the limitations of qualitative analysis, which is highly operator-dependent, the current work aims to conduct a quantitative analysis, evaluating, through micro-CT, age-related trabecular and cortical microstructural alterations of the sternoclavicular joint, on both its clavicular and sternal ends, in order to establish a more reliable and objective analytical method for age-at-death estimation in adults.

Fifty-nine sterno-clavicular joints from deceased individuals (30 males and 29 females), divided into three age-at-death ranges (≤40 years, 41-59 years, ≥60 years), were analyzed using high-resolution Micro-CT. Microstructural parameters of trabecular and cortical bone were assessed using CTAn Software on both the clavicle and sternum, including Bone Mineral Density (BMD), Bone Volume Fraction (BV/TV), specific Bone Surface for a given VOLUme (BS/BV), Connectivity (Conn), mean Structure Thickness (St.Th), Intertrabecular Spacing (St.Sp), and Degree of Anisotropy (DA). One-way Analysis of Variance (ANOVA) with Bonferroni correction was applied to assess potential differences among age groups.

Results revealed significant age-related microstructural trabecular and cortical changes in both clavicular and sternal bones, with most parameters showing statistically significant discriminatory power among the three age categories. Specifically, trabecular BMD and cortical BV/TV and St.Th decreased, whereas trabecular St.Sp increased with age in both sexes. Conversely, trabecular BV/TV and St.Th showed age-related decline only in males in both bones, suggesting sex-specific differences in bone microstructural aging, likely influenced by hormonal regulation. Furthermore, trabecular and cortical BS/BV and trabecular DA correlated with age only in the sternum, indicating site-specific bone remodeling patterns. These findings support micro-CT evaluation of age-related microstructural alterations of the sternoclavicular joint as a valid and promising method for age-at-death estimation. When combined with qualitative assessment of external morphological degenerative alterations of the sternoclavicular joint, this method offers a comprehensive and integrated qualitative-quantitative approach that enhances objectivity and reliability of age-at-death estimation in adults.

A68 Using Information Theory to Better Understand the Relationship Between the Cranial Phenotype and Group Membership

Christopher A. Wolfe, PhD, East Carolina University, Greenville, NC; Kyra E. Stull, PhD, University of Nevada, Reno, Reno, NV*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the relationship between craniometric variables and group membership. Attendees will also gain an understanding of the utility of information theoretic metrics when designing and applying forensic anthropology methods.

Impact Statement: After attending this presentation, attendees will have a better understanding of the relationship between craniometric variables and group membership. Attendees will also gain an understanding of the utility of information theoretic metrics when designing and applying forensic anthropology methods.

Abstract Text: Information theory quantifies the degree of uncertainty or surprise in data.[1] In studies of population affinity, information theory relates to how well the skeletal phenotype transmits or communicates the correct group membership. In this study, we quantify the degree of uncertainty in craniometric variables using measures of entropy and quantify the combined relationship between craniometric variables and group membership using mutual information. We utilize the William W. Howells Craniometric data set (n = 2,524) to estimate the information content between 22 craniometric variables and 30 population groups.[2] Univariate Bayesian mixed effects models were fit in Stan to each individual measurement where the mean and standard deviation were allowed to vary by population (G = 30).[3] A multivariate Bayesian mixed effects model was also fit to all variables to determine any difference in information gain between univariate and multivariate settings. All probabilistic results were used to calculate the Shannon entropy of group membership, the differential entropy of craniometric measurements, and the mutual information between measurement and group membership. Conditional entropy was also quantified to describe how much information is gained if either response or group was held constant with lower values indicating less uncertainty and high association between variables. Analyses were run separately for biological males and females to account for any differences related to sexual dimorphism.

Results suggest that all Interlandmark Distances (ILDs) are informative of group membership (0.1-0.5 bits of information). There are no patterns related to anatomical cranial regions or functional regions. Larger variables (e.g., cranial lengths or breadths) display larger levels of entropy and noise as compared to those of smaller variables (e.g., nasal breadth). Results are similar between biological males and biological females. Multivariate results show that there is shared information between craniometric variables and population variables (4.57 bits) that approaches the entropy (or variability) of the population variable (4.84 bits). The similarity between these bits suggests that multivariate outcomes are more informative of group membership than any one trait individually. Further, individual and multivariate ILDs display varying levels of conditional entropy indicating that certain trait(s) are more or less informative of a given group membership.

This study reveals strong alignment between cranial dimensions and group membership and subsequently supports the utility of craniometric variables in population affinity estimation. Additionally, the findings reinforce the notion that multivariate models are most informative when considering population membership. Importantly, the use of information theory in forensic anthropology moves the field away from the restrictive model-bound assumptions in traditional approaches (e.g., linear discriminant analysis) and allows for a full probabilistic approach that provides for a deeper understanding of the skeletal phenotype. Further, while the current research posits the link between information content and predictive ability, it moves the field beyond debated notions of "classification accuracy" and, in turn, leads to a fuller appreciation of the relationship between the cranium and group membership.

A69 Exploring Population Affinity in United States Asian Populations

Amelia Konda, MA, Michigan State University, East Lansing, MI; Joseph T. Hefner, PhD, MSU, East Lansing, MI; Kate Spradley, PhD, Forensic Anthropology Center at Texas State University, San Marcos, TX; Matthew C. Go, PhD, SNA International, supporting the DPAA, Joint Base Pearl Harbor-Hickam, HI*

Learning Objectives: After attending this presentation, attendees will be familiar with population structures among American Asian and Asian samples from abroad. Our goal is to quantify levels of heterogeneity among these samples.

Impact Statement: This presentation will impact the forensic community by demonstrating a need for more nuanced reference data. The purpose of those data is to account for environmental, gene flow, and intra-group variation influences on cranial morphology among Asian populations encountered in forensic anthropological casework.

Abstract Text: The biological profile comprises four estimated components: population affinity, age, sex, and stature. Age, sex, and stature are generally considered population-specific estimates, matching detectable patterns of human variation among different population structures. To select the most appropriate age, sex, and stature estimation methods, forensic anthropologists estimate an individual's population affinity and then choose the method with the most appropriate reference sample data. When practitioners report population affinity, they are statistically evaluating the genetic and environmental influences expressed within the hard tissues as a proxy for social race.

To emphasize the necessity of population affinity over the more generalized geographic ancestry, we compared American-born (n = 45) and born-abroad (n = 719) populations to assess homogeneity within and between each. These populations included samples from multiple international documented skeletal collections representing Asian Indian, Chinese, Filipino, Japanese, Korean, and Vietnamese born individuals. Interlandmark Distances (ILDs) were also collected from 3D models of Computed Tomography (CT) images for Asian individuals born in the United States using the New Mexico Decedent Imaging Database (NMDID). These data sources were compared using Mahalanobis Distance, Canonical Variates Analysis (CVA), canonical structure coefficients, classification statistics, and graphical representation.

An initial Multivariate Analysis of Variance (MANOVA) identified significant differences in cranial morphology by sex, Population Affinity (PA), and their interaction (Sex: Pillai's trace = 0.369, $F(16,738) = 26.99$, $p < 0.001$; PA: Pillai's trace = 1.073, $F(80,3710) = 12.67$, $p < 0.001$; Sex × PA: Pillai's trace = 0.234, $F(64,2964) = 2.87$, $p < 0.001$). CVA coefficient loadings identify nasal height (0.8036, 0.4126), upper facial height (0.5972, 0.2064), and orbital height (0.5814, 0.3656) as key contributors to population differentiation along the first two CV axes accounting for over 65% of the variation in the sample. The CVA also suggests South Asian populations exhibit more distinct cranial morphology, while East and Southeast Asian populations tend to cluster more closely to each other. A divergence between American-born Japanese and the Japan-born sample suggests gene flow, urbanization, and developmental plasticity could potentially contribute to measurable changes in cranial morphology, at least for the Japanese sample. While our complete sample does not capture all aspects of the Asian diaspora, these data do represent an initial assessment of homogeneity among United States- and foreign-born Asian individuals, and they indicate a need for additional research and future exploration.

Finally, classification models performed moderately well, but disappointed for populations underrepresented in current reference datasets (e.g., FORDISC), as expected. The frequent misclassification of Filipino and Vietnamese individuals (correct classification accuracy: 0.0% and 50.0%, respectively) highlights the need for more comprehensive reference datasets and underscores the importance of caution when interpreting population affinity assessments in medicolegal cases.

Moving forward, forensic anthropology researchers should prioritize expanded, contemporary reference datasets that more accurately reflect modern United States populations. Ultimately, this study contributes to the growing body of literature calling for greater inclusivity and methodological refinement in forensic anthropology, ensuring population affinity estimation methods remain rigorous, ethically responsible, and forensically useful in an increasingly diverse world.

A70 Unrepresented and Misclassified: Evaluating FORDISC 3.1 Using Korean Crania

Yangseung Jeong, PhD, University of Tennessee, Knoxville, TN; Addison Springer, BA, University of Tennessee, Maryville, TN*

Learning Objectives: After attending this presentation, attendees will learn how to critically interpret FORDISC outputs when analyzing skeletal remains from populations not included in its reference database. They will understand how Posterior Probability (PP), Typicality (TY), and Correct Classification Rate (CCR) can be used collectively to identify potential misclassifications and recognize cases that warrant further scrutiny.

Impact Statement: This presentation will impact the forensic science community by highlighting the limitations of FORDISC when applied to skeletal remains from unrepresented populations. It introduces a practical framework for interpreting ambiguous classification results using PP, TY, and CCR. In doing so, it encourages more cautious and evidence-informed reporting practices. Ultimately, this work promotes greater accuracy and accountability in population-affinity estimation within forensic anthropology.

Abstract Text: Population affinity estimation is a critical component of forensic anthropological practice in the United States, and FORDISC is among the most widely employed tools for this purpose.[1] Despite its utility, FORDISC's accuracy is inherently constrained by the populations included in its reference database. As the demographic composition of the United States continues to diversify, there is a growing likelihood that skeletal remains encountered in forensic casework may belong to individuals from populations not represented in FORDISC. In such cases, reliance on FORDISC without recognizing its limitations can result in confidently reported yet incorrect classifications.

This study examines how FORDISC classifies skeletal remains from an unrepresented population and assesses whether there are diagnostic patterns in its outputs that may alert practitioners to such cases. A total of 101 modern Korean male crania, whose ancestry is not included in FORDISC, were analyzed. FORDISC results were evaluated based on three key outputs: PP, TY, and CCR. Since FORDISC cannot correctly classify individuals from unrepresented groups, all assignments were, by definition, erroneous. However, the central question was whether these erroneous classifications were presented with high confidence, thereby risking misinterpretation.

Results showed a high degree of inconsistency in FORDISC's classifications. Korean skeletons were variably assigned to a range of groups, including Vietnamese, Chinese, and Guatemalan, with no consistent pattern across cases. This inconsistency suggests that FORDISC does not reliably assign skeletons to their nearest geographical neighbors when those populations are absent from the reference database.

To assess the potential for identifying such cases, various threshold values for PP, TY, and CCR were tested. When using PP alone, a cut-off of 0.8 yielded an error rate of 20.8%, meaning that over one in five Korean skeletons were classified with seemingly high confidence into an incorrect group. Incorporating TY of 0.05 as a cut-off alongside PP reduced the error rate to 12.9%. Adding a CCR threshold of 75% further reduced misclassifications with confidence to zero. These results demonstrate that a combination of low PP, TY, and CCR values can serve as potential indicators that a skeleton may originate from a population not represented in FORDISC.

It is important to emphasize, however, that low values of PP, TY, or CCR should not be interpreted as definitive evidence of unrepresented ancestry as genuine reference cases may also produce such results. Rather, these metrics should be viewed as cautionary signals warranting careful consideration of the possibility that the individual does not belong to any of the reference groups included in the database.

In conclusion, although FORDISC lacks the ability to accurately classify skeletons from unrepresented populations, its output, when critically evaluated, can offer meaningful insight. This study provides empirical guidance on interpreting ambiguous FORDISC results and highlights the importance of recognizing the tool's limitations in the context of an increasingly diverse society.

A71 Automated Craniofacial Reconstruction Through the Use of Generative AI: The FaceGen Project

Oscar Ibáñez, PhD, Universidade da Coruña, Galicia, Spain; M. Alejandra Guativonza Higuera, MSc, University of A Coruna, Torrelavega, Cantabria, Spain; Javier Venema, MSc, Panacea Cooperative Research, Granada, Andalucia, Spain; Andrea Valsecchi, PhD, Panacea Cooperative Research, Ponferrada, Castilla y Leon, Spain; Pablo Mesejo, PhD, DaSCI Research Institute, Granada, Andalucia, Spain; Guillermo Gómez-Trenado, PhD, DaSci, Granada, Andalucia, Spain; Stéphane Lathuilière, PhD, INRIA, University Grenoble Alpes, Grenoble, Auvergne, France*

Learning Objectives: Attendees will explore different approaches to the problem of Craniofacial Reconstruction (CFR), illustrating the potential of different generative AI techniques, while discovering their limitations in relation with the type of inputs that can be used to represent craniofacial structures. Additionally, attendees will learn about how these models can be tested to support their usefulness in human identification efforts, the challenges of mathematically represent human perception of images, and those associated with enhancing the trustworthiness of generative models.

Impact Statement: This presentation will impact the forensic science community with key aspects of AI deployment in relation to the high requirements for forensic applications. It will provide an overview of the similarities and the differences between different techniques that are not widely known and are often viewed under the general umbrella of generative AI, highlighting their strengths and limitations for automating CFR.

Abstract Text: CFR is an identification technique that allows reconstructing facial appearance only from the skull structure, of special relevance in situations where there are no reference data or samples (e.g., medical records, family DNA). The main objective of this work is to develop a reliable and objective method, comparing different strategies based on the use of generative AI, that allow the automation of CFR and its forensic use.

With that aim, three strategies have been followed: (1) the use of Generative Adversarial neural Networks (GANs) with volumetric images (3D), (2) the use of GANs with multi-view depth maps (2.5D) building up on the work of Pan et al., and (3) the use of diffusion models.[1] The training has been carried out on a sample with more than a thousand examples sourced from public repositories (New Mexico Decedent Image Database [NMDID]) and collaborations (National Forensic Service [NFS] Seoul), facilitated by access to the computational resources of EuroHPC (MNS 5, BSC).

Preliminary results point to superior performance of 2.5D GANs compared to the rest in terms of quality and fidelity to the real image. Within this approach, the best results so far have been obtained by using three views of the skull model (-30, 0, and 30 degrees) as input, in combination with the use of Wasserstein GAN with gradient penalty (WGAN-GP) in training. In a cross-comparison of CFR outputs and ground truth images, a ranking of correspondence was calculated combining different metrics (Mean Absolute Error [MAE] and perceptual loss) placing the correct identity in position 4.88 as average. In summary, the use of GANs on 2.5D images constitutes a promising strategy for the development of an automatic CFR tool for forensic use, given that it also offers lower computational costs and environmental impact than other computationally intensive approaches. These results form the basis for future developments towards a photorealistic CFR tool.

A73 Introducing MOSAIC: Methods of Sex, Stature, Affinity, and Age for Identification Through Computational Standardization

Joseph T. Hefner, PhD, MSU, East Lansing, MI;Kate M. Lesciotto, PhD, University of North Texas Health Science Center, Fort Worth, TX; Michael W. Kenyhercz, PhD, Phokus Analyica, Lakewood, OH; Heather Edgar, PhD, University of New Mexico, Albuquerque, NM; Kate Spradley, PhD, Forensic Anthropology Center at Texas State University, San Marcos, TX; Alexandra R. Klales, PhD, Washburn University, Topeka, KS*

Learning Objectives: After attending this presentation, attendees will be familiar with MOSAIC, a computer program being developed that is capable of outperforming other methods of forensic anthropological analysis by combining a matched skeletal dataset with machine learning and artificial intelligence for the construction of a holistic biological profile.

Impact Statement: This presentation will impact the forensic community through the introduction of a pilot version of MOSAIC as a non-proprietary algorithm to overcome method fragmentation and unmatched reference samples. MOSAIC provides demonstrable and consistent outperformance of traditional approaches, which underscores the importance of interrelated data to improve accuracy. The final MOSAIC product will include publicly releasing both the dataset and code to promote transparency, reproducibility, and collaborative refinement. As MOSAIC matures to include stature and age, it promises a unified, efficient pipeline to reduce analytical complexity and support more consistent reporting practices.

Abstract Text: Forensic anthropologists use various approaches to estimate the biological profile of unidentified human remains. However, these methods typically focus on a single profile parameter, use different types of data (e.g., cranial metric, cranial non-metric), are based on different population samples, and use a wide variety of statistical approaches. As such, practicing forensic anthropologists face a bewildering array of methods that can produce idiosyncratic results. This leaves analysts with no way to determine how differing results from each method should be weighed or reported. Finally, compartmentalized data types, for example pre-determining that pubic bone morphology is only useful for sex estimation, does not leverage known interactions between multiple biological profile parameters.

MOSAIC is a non-proprietary algorithm used to produce a holistic estimation for all four biological profile parameters. The purpose of MOSAIC is to refine forensic anthropological practice and provide a unified method standardizing the estimation of the biological profile for unknown skeletal remains. To do so, MOSAIC is being developed as an open source, matched skeletal dataset containing metric and non-metric variables of the skull, dentition, and postcranial skeleton within a Machine Learning and Artificial Intelligence (ML/AI) model for simultaneously estimating all four parameters of the biological profile. We hypothesized that ML/AI environments would provide a more reliable biological profile estimation than current compartmentalized approaches.

To conduct a proof-of-concept study, existing data were pooled to identify individuals with available cranial and postcranial metric (sex and affinity), cranial non-metric (sex and affinity), and postcranial non-metric (sex) data. The partial matched dataset of 205 individuals represents a small sample of modern American Black, Hispanic, and White individuals (BF=19, BM=49, HF=21, HM=37, WF=38, WM=41) used to demonstrate the efficacy of an alpha-version of MOSAIC.

For comparative purposes, we generated baseline results using FORDISC 3.1, MorphoPASSE, MaMD Analytical 1.0, and (hu)MANid.[1-4]. The alpha MOSAIC model comprised a series of Random Forest Models (RFM) developed using the randomForest SRC package in R.[5] (Each model utilized 500 trees and four variables at each node. In every instance, MOSAIC outperformed the traditional approaches, and, most importantly, did so using all available traits and measurement data rather than compartmentalizing each data type. MOSAIC achieved 97.56% accuracy in sex estimation (200/205), 94.15% in affinity estimation (193/205), and 90.24% in combined affinity × sex (185/205), outperforming MorphoPASSE (88.9% skull sex, 92.0% innominate sex), MaMD Analytical (89.3% affinity), FORDISC (85.85% affinity, 76.8% affinity x sex), and (hu)MANid (43.0% affinity × sex).

These results highlight the importance of interrelationships within the matched dataset. In other words, valuable information is lost when using traditional approaches that compartmentalize data into individual biological profile components. These preliminary results are limited to population affinity and sex, due to a limited sample, thus highlighting the need for a large, matched dataset. MOSAIC's final form will expand to provide a single workflow to estimate sex, stature, affinity, and age.

A74 Something Old, Something New, Something Borrowed: Interpretable Deep Learning for Forensic Sex and Age Estimation

Željana Bašić, PhD, Faculty of Forensic Sciences, University of Split, Split, Splitsko-Dalmatinska, Croatia; Ivana Kružić, PhD, Faculty of Forensic Sciences, University of Split, Split, Splitsko-Dalmatinska, Croatia; Ivan Jerković, PhD, Faculty of Forensic Sciences, University of Split, Split, Splitsko-Dalmatinska, Croatia*

Learning Objectives: After this presentation, the participants will gain insight into the Deep Learning (DL) architectures used in forensic anthropological studies for sex and age estimation based on different image inputs. They will evaluate methods of assuring models' interpretability, which bridge the issue of the black-box approach and enable anthropologists to study and interpret them in the light of anthropological traits and standards.

Impact Statement: This presentation strengthens the competencies of scientists and practitioners in the field of anthropology by demonstrating how the methods based on state-of-the-art technologies and artificial intelligence relate to the fundamental anthropological practices and standards. The proposed approach, based on the implementation of interpretability tools and the involvement of experienced practitioners in such studies, contributes to enhancing credibility, transparency, and ethical practice in everyday case work and method advancements.

Abstract Text: DL has transformed forensic anthropology by automating age and sex estimation from bone images, but its black-box nature raises concerns about its forensic admissibility. This presentation explores interpretable DL applications, aligning with the AAFS 2026 theme, Back to Basics, by prioritizing transparency, the integration of field knowledge into automated biological profiling, and ethical forensic practice.

To address the challenge of DL's opacity, we first examined the current state of research on automated age and sex estimation. A synthesis of 28 studies (21 on sex and 7 on age estimation) revealed DL's potential in analyzing images of skeletal elements (e.g., Computed Tomography [CT], ML/AI [MRI], X-ray, and photogrammetry) for forensic sex and age estimation. Convolutional neural networks trained on 2D or 3D models dominated, reaching respectable accuracies (many of them ≥ 95%). However, less than half of them (39.2%) used interpretability methods like Gradient-weighted Class Activation Mapping (Grad-CAM) or 3D saliency maps, raising concerns about forensic acceptance.[1,2] These studies focused on bones like the pelvis, skull, and clavicle, highlighting biologically relevant features, providing anatomical visualizations, and region-of-interest mapping. While these studies show promise, the limited use of interpretability underscores the need for transparent DL methods.

The research at the University of Split addresses this gap. The Laboratory of Forensic and Biological Anthropology advances interpretable DL for sex and age estimation. One study used deep learning-based image embedding with Principle Component Analysis (PCA) on medial clavicle CTs to classify individuals above or below 30 years, achieving 92.5% accuracy with visual clustering of morphological age-related patterns.[2] Another applied an adapted PointNet++ network to 3D hyoid bone models, yielding 88.7% accuracy for sex estimation, with 3D saliency maps revealing sex-specific morphological differences.[3] The visualizations, validated by anthropologists, align model outputs with field knowledge and standards, enhancing transparency. These approaches embody technical innovation ("something new") while upholding anthropological knowledge and standards ("something old"), and their integration of computer vision and software engineering ("something borrowed") bridges emerging technologies with forensic fundamentals.[4]

Based on these findings, a framework is proposed to ensure that interpretable DL is reliable and usable across forensic contexts. DL interpretability is evaluated using standardized metrics (e.g., measures of feature importance), validation against anthropological expertise, and practitioner feedback regarding usability. This framework promotes alignment with forensic reasoning and ethical standards, thereby reinforcing disciplinary trust and enhancing the reliability of DL applications in judicial settings.

A75 Combining the Micro With the Macro: Age Estimation Using Machine Learning Methods With Histological Variables and Traditional Indicators

Sophia R. Mavroudas, PhD, Forensic Anthropology Center at Texas State, San Marcos, TX; Lauren Meckel, PhD, Texas State University, San Marcos, TX; Nicholas P. Herrmann, PhD, Texas State University, San Marcos, TX; Justin Z. Goldstein, PhD, NYC Office of Chief Medical Examiner, New York City, NY*

Learning Objectives: After attending this presentation, attendees will learn how combining gross and histological data can contribute to a holistic skeletal age-at-death estimate when compared to analyzing such data in isolation.

Impact Statement: This presentation will impact the scientific community by exemplifying how more data from existing epiphyseal union sites, degenerative skeletal methods, and histological methods should be collected from the same individuals to improve age-at-death estimation.

Abstract Text: Anthropologists have attempted to create methods for skeletal age-at-death estimation that combine various areas of the skeleton, however, to date few have incorporated histological data. This study explores the relationship between gross and histological age indicators from the same individuals across various published age-at-death estimation methods, providing a model for future development of a novel method that incorporates skeletal senescence indicators from all scales of bone tissue. The aim was to counterbalance method bias through incorporating variables that are uniquely correlated to skeletal age into one age-at-death estimation method.

Specifically, this study utilized macroscopic and microscopic age data from a known age-at-death sample of 271 individuals from across North America, including the United States and Mexico. Variables evaluated include epiphyseal closure of the medial clavicle, pubic symphysis phase, and histological variables from the 6th rib, including osteon population density (OPD), intact OPD, fragmentary OPD, drifting OPD, relative cortical area, osteon area, and osteon circularity.[1-5] The accuracy of the methods were tested individually and in a combined gross and histological method using a Random Forest (RF) model. The results show that individually, the gross age methods perform well ranging in accuracy from 99% for clavicle to 65% for one of the pubic symphysis methods[1,2]. The histological aging methods performed strongly with an accuracy ranging from 91% to 86% depending on the method.[4,5]

After testing these methods individually, an RF model was constructed to classify age into four different age cohorts, including < 35 years, 35-50 years, 50-75 years, and 75+ years. The RF model combined gross and histological data in a leave-one-out approach. Results showed that the RF model performed with 61% accuracy across the entire sample with Osteon Population Density (OPD) being the most important variable in most cases. The RF model performed with the highest accuracies for the < 35 years and 75+ year cohorts. The accuracy of the RF model for predicting age was then compared against the gross morphological methods by age group. Results showed that when looking at the four age groups across all methods, including the RF model, the highest accuracies were 94% for the < 35 years cohort, 100% for the 35-50 year cohort, 90% for the 50-75 year cohort, and 68% for the 75+ year cohort from the RF model for which OPD was the most important variable.[1,3] Considered collectively, these results show an encouraging trend for incorporation of both macro and microscopic data into age estimation methods for forensic anthropology in North America.

A76 Applying Machine Learning Models in Forensic Anthropology for Sex Estimation From Long Bone Diaphysis Shape

Melanie M. Beasley, PhD, Purdue University, West Lafayette, IN; Talha Mahmud, MS, Purdue University, West Lafayette, IN; Fengqing M. Zhu, APM, Purdue University, West Lafayette, IN*

Learning Objectives: After attending this presentation, the attendees will have a better understanding of how Machine Learning (ML) tools can be used for estimation of sex from long bone diaphysis fragments of unknown human remains. The attendees will also learn how Computed Tomography (CT) scan images are processed and used in ML models for broader applications in forensic anthropology.

Impact Statement: The presentation will impact the forensic science community by presenting results from ML tools applied to questions of the biological profile of unknown human remains when only long bone diaphysis fragments are available. The presentation will provide an effective approach to utilize CT scan data and ML tools to estimate the sex of decedents without the need for a complete bone.

Abstract Text: Traditional osteological methods to estimate sex rely heavily on the pelvis and cranium, which exhibit high accuracy rates (>90%) for unidentified skeletal remains. However, in many forensic cases, these bones may be missing or damaged by trauma or postmortem taphonomic processes preventing the use of traditional methods. In such situations, long bones (i.e., femur or humerus), become alternatives for determining biological sex. Yet, these methods require complete bones with undamaged epiphyses. New ML approaches, with 92% accuracy rates, for sex estimation from long bones also require complete elements [1], limiting their application to fragmented remains.[1]

This presentation aims to address the challenge of requiring complete long bones by introducing a method that utilizes diaphysis geometric shape differences. CT scan data from the New Mexico Decedent Image Database (NMDID) database of males (n = 15) and females (n = 15) were converted into 3D long bone diaphysis files. These files were later cleaned, scaled, and aligned to derive the following five geometric features: centroid, skewness, variance, curvature angle distribution, and volume-surface ratio. These features were fed into seven individual ML models (random forest, support vector machine, k-nearest neighbor, xgboost, gradient boost, logistic regression, and lightgbm) for sex estimation, thus removing the reliance on complete intact long bones.

Results from this initial pilot study suggest that cross-sectional properties of bones contain rich, sexually dimorphic features that have been largely underutilized by ML tools in forensic science. The study demonstrates how these features can enable reliable sex estimation using ML models that are comparable to other traditional anthroposcopic and anthropometric methods. Using the five geometric features, the proposed ML models achieve 91.67%, 85%, 85%, and 83.33% accuracy from the humerus, femur, tibia, and fibula, respectively. The radius and ulna were excluded in this analysis due to inconsistent alignment in the CT scan data, resulting in wave distortions in the extracted files. The presentation will also demonstrate that fragments with smaller cross-sectional areas lead to a consistent performance decline of up to 6.67%. This shift from reliance on complete bones or features to geometric features of diaphysis fragments opens new avenues for identification methods, especially in cases involving highly fragmented remains.

Furthermore, the presentation will highlight how this approach addresses a major bottleneck in the development of ML applications in forensic anthropology: the scarcity of large, high-quality datasets. By utilizing CT scans from existing medical archives, a scalable and non-invasive solution will be introduced to collect training data efficiently. This method will promote digital repositories, boost accessibility, reproducibility, and collaboration in forensic science.

The results confirm that integrating advanced imaging technologies with ML tools can significantly improve osteological sex estimation of fragmented remains, achieving performance comparable to traditional and early ML approaches. The presentation will teach participants how this approach can enhance forensic practice by enabling faster, more accurate, and less invasive analysis of human remains. Ultimately, this work aims to contribute to the advancement of forensic science through innovative methodologies that improve sex estimation in both archaeological and forensic contexts.

A77 An Assessment of Subadult Skeletal Growth and Development Based on a Michigan Medical Examiner Sample

Megan E. Carroll, BS, Northern Michigan University, Marquette, MI*

Learning Objectives: After attending this presentation, attendees will be informed about the accuracy of skeletal age estimations derived from radiographic long bone measurements, based on comparisons with known chronological ages.

Impact Statement: This presentation highlights the reliability of radiographic long bone measurements in forensic age estimations. It will impact the forensic science community by emphasizing the importance of validation studies when working with biological variables that may be dependent on developmental and environmental factors.

Abstract Text: A high rate of subadult cases in the Medical Examiner's Office (MEO) may indicate common underlying factors. During postmortem exams, basic anthropometric measurements are taken, including weight and length (measured crown to heel); some offices also routinely capture radiographic images or Computed Tomography (CT) scans. In cases involving unidentified subadults, age at death is often estimated through dental development or long bone measurements. The methods available for age estimation from long bone measurements, however, are not based on data from modern populations and may not reflect secular change.

This study involves the analysis of radiographic images from 235 cases involving subadults aged 0-12 years who were investigated by the Western Michigan University Homer Stryker M.D. School of Medicine, Department of Pathology (WMed) MEO. The objective of the study was to determine how well the skeletally estimated age of subadults whose deaths were investigated by a Michigan MEO aligned with their known chronological ages. The analysis was based on long bone measurements from radiographs that were collected during the postmortem examinations at the MEO. Paired t-tests used to analyze is there was any statistical difference between the chronological and skeletal age based on radiographic measurements. Results from these comparative analyses indicated that for the humerus (paired $t=1.10$, $df=233$, p-value=0.27), radius (paired $t=0.07$, $df=230$, p-value=0.94), and ulna (paired $t=0.46$, $df=228$, p-value=0.65), there was no statistical difference between the chronological and skeletal ages. Bland-Altman plots were used to identify discrepancies between chronological age and skeletal age. Statistical outliers were identified, and further analysis shows the differences ranged from less than 2 years of age to less than 7 years.

Results from this study indicate that the humerus was the more reliable for skeletal estimation, followed by the radius and ulna, respectively. While several outliers were statistically determined, further analysis into the specific cases identified as outliers will be necessary to evaluate whether these cases display large enough differences between the skeletal and chronological ages to affect age estimation.

A79 A Foundational Analysis of Practitioner Decision-Making and Interaction With FORDISC

Marion Davidson, MSc, University College London, Baltimore, MD; Micayla C. Spiros, PhD, DC Office of the Chief Medical Examiner, Washington, DC; Sherry Nakhaeizadeh, PhD, University College London, London, England, United Kingdom; Ruth M. Morgan, DPhil, University College London, London, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will have an understanding of the variation that exists in the decision-making processes among forensic practitioners when using and interacting with the application FORDISC.

Impact Statement: This presentation will impact the forensic science community by providing new insight into the decisions of forensic anthropologists to increase transparency in analytical processes, improve the reliability of method application, and contribute to the development of best practice recommendations.

Abstract Text: The continued professionalization of forensic anthropology necessitates a comprehensive understanding of examiner decision-making and the interpretation processes during analyses. FORDISC, a statistical software program, is reported as the most practiced method for population affinity estimation and the most preferred metric approach to sex estimation.[1,2] While FORDISC is often considered objective and has demonstrated accuracy in casework, it retains a level of subjectivity due to the human factors involved in the analytical decisions.[3] Moreover, it is a user-driven software analysis.[4] That is, FORDISC is a statistical program that relies on the active decisions of the forensic anthropologist using the program to drive statistical analyses. These decisions lead to results which must then be interpreted by the practitioner. Understanding how forensic anthropologists interact with the program is an important aspect in improving the reliability of method performance.[5,6]

Ten participants responded to an anonymous survey that aimed to examine the decision-making processes among forensic anthropologists using FORDISC. Of the respondents, 7 held doctorate degrees, 9 reported being very or extremely experienced with using the program, 9 reported being confident or very confident with using it, all 10 received training in FORDISC, and 4 were American Board of Forensic Anthropology (ABFA) certified. Respondents received an Advantage data file (*.adt) of 33 cranial and mandibular measurements and were instructed to perform their analysis as they would in casework until reaching their final iteration. Participants were informed the individual was male in order to mitigate decision-making analysis. They also answered several questions regarding their typical decisions when using FORDISC.

Preliminary results reveal variation in practitioner interaction with the program. Half of the participants began their analysis with only male population groups, while the other half began with all population groups (e.g., male and female). Across all iterations, 30% of participants exclusively used linear Discriminant Function Analysis (DFA), 30% applied a stepwise selection of measurements, and 50% excluded individual outliers during the analytical process. In the final iteration, the number of population groups included ranged from 2 to 8 while the number of measurements ranged from 14 to 23. Moreover, two participants had measurement outliers present in their last run that was three standard deviations away from the mean. This presentation will discuss these findings as well as how measurements and population groups were removed from iterations, how the number of measurements adhered to the minimum suggested amount based on the number of selected groups, and how the probability outputs compared to the recommendations from the FORDISC Help File.

This initial study demonstrates the existing variability in which self-reported experienced practitioners interact with FORDISC, highlighting the subjective human factors that impact the application of forensic methods. A comprehensive understanding of these variations and how analysts interact with these statistical models is imperative. Insights into these decision-making processes will allow for the continued improvement of analytical methods, training programs, and best practice development.

A80 Breaking Down Expertise: How Experience Shapes Sex Estimation in Forensic Anthropology

Nicole A. Mantl, MSc, University College London, London, England, United Kingdom; Sherry Nakhaeizadeh, PhD, University College London, London, England, United Kingdom; Ruth M. Morgan, DPhil, University College London, London, England, United Kingdom*

Learning Objectives: After attending this presentation, participants will have a clear understanding of variation in task-specific decision-making and the impact of experience and expertise on sex estimation from the skull.

Impact Statement: This presentation will impact the forensic science society by providing greater insight into visual evidence-based decision-making and how forensic anthropologists set about making inferences when estimating sex from the skull.

Abstract Text: Growing concerns over the transparency of forensic reporting have led to a renewed emphasis on simplifying decision-making processes and making them more explicit.[1,2] This is particularly relevant for visual non-metric methods such as sex estimation, where subjectivity and observer experience play significant roles.[3,4]

This study investigates the interplay between intuitive and reflective decision-making in sex estimation from the skull. The study explored three key themes: (1) how experience affects decision-making strategies: (2) the relationship between experience, accuracy, and confidence; and (3) the influence of expertise-building factors—such as forensic casework experience, 3D modeling, and academic background—on the likelihood of accurate sex estimation.

Participants, including practicing forensic anthropologists, academics, and students , assessed ten digitally rendered 3D skulls derived from Computed Tomography (CT) scans of a modern New Mexico population.[5] Each participant provided an initial intuitive judgment under time pressure (five seconds), followed by a full assessment, scoring skeletal sexual traits on a five-point scale, and—if applicable—offering their expert opinion.[6]

Results indicate no significant difference between intuitive (gut feeling) and methodical sex estimations. While methodical scoring improved accuracy by approximately 5%, the clarity and complexity of sexually dimorphic features on the skull had a greater influence on both accuracy and consistency. Skulls with clear traits achieved high agreement, whereas ambiguous skulls resulted in lower accuracy and inconsistent outcomes across both decision-making approaches.

Experience did not significantly enhance accuracy, though years of practice correlated with higher confidence. Interestingly, experts were more prone to overconfidence, whereas novices tended to underestimate their performance. Participants often relied on a holistic evaluation of the skull, emphasizing key features such as the glabella and mastoid processes. This heuristic strategy highlights how formal training evolves into tacit expertise but also underscores subjective biases inherent in visual assessment methods.

These findings contribute to a better understanding of the cognitive processes behind expert judgment in forensic anthropology and emphasize the need for transparent, evidence-based approaches to improve reliability in visual sex estimation.

A81 Areas of Interest: Eye-Tracking in Forensic Anthropology Sex Estimation

Nicole A. Mantl, MSc, University College London, London, England, United Kingdom; Sherry Nakhaeizadeh, PhD, University College London, London, England, United Kingdom; Ruth M. Morgan, DPhil, University College London, London, England, United Kingdom*

Learning Objectives: After attending this presentation, participants will understand how to interpret gaze-pattern data to distinguish decision-making strategies to assess how visual search strategies influence consistency, speed, and accuracy in forensic analysis.

Impact Statement: This presentation will impact the forensic science society by revealing how cutting-edge technology can be used to investigate visual attention, perception, and decision-making processes and how these influence the accuracy of sex estimation from skull morphology, offering insights to improve expert training and analysis reliability.

Abstract Text: Human identification is a cornerstone of forensic science, where determining the biological profile of skeletal remains can be critical in both legal and humanitarian contexts.[1,2] Among these tasks, estimating biological sex from skull morphology is a fundamental yet visually demanding process that requires both precision and expertise.[3]

This study explores the cognitive and perceptual mechanisms—such as visual attention, gaze patterns, and decision-making—that underpin these assessments. Using eye-tracking technology alongside established forensic anthropology methods, the study explores the psychological nature expertise, specifically during the estimation of biological sex from skull morphology. A group of 15–20 participants, consisting of a focus group of expert observers (practicing professionals and academics from the United States and the United Kingdom, identified through published lists of certified individuals), assessed digital images of four skulls (3D models of Computed Tomography [CT] scans of modern population) using established and commonly used non-metric visual examination methods and discriminant functions.[4-8]. Eye-tracking metrics, such as fixation duration and count, and area of interest visit duration and count, were recorded to map participants' gaze patterns and attentional focus on morphological features. Decision outcomes, confidence levels, and response times were also captured to evaluate the relationship between visual behavior, expertise, and estimation accuracy.

Preliminary findings from the study suggest that years of experience with sex estimation is not a direct impact factor on visual interpretation or accuracy of outcome. The eye-tracking data appears to suggest a general predilection for global visual examination, in particular from the frontal and left lateral views. Feature-specific analysis suggests a focus on the frontal bone (including the glabella), followed by the shape of the orbits bone and parietals, as both greatest number of visits and fixation duration.

Conclusions drawn from the results of the study will be discussed in relation to three key themes: (1) how visual attention mechanisms influence forensic decision-making; (2) the balance between global and local visual perception and the role of cognitive strategies (intuitive vs. analytical thinking) in expert judgments; and (3) how expertise shapes attentional focus, gaze efficiency, and decision accuracy on traditional visual methods used in skull sex estimations.

These findings will contribute to a better understanding of the methodological and cognitive processes behind expert judgment in forensic anthropology emphasizing the potential impact of first impressions and its potential impact on the consistency and reliability of forensic assessments.

A82 Combining Intracortical Porosity, Histomorphometric, and Toxicological Data to Describe a Profile of Bone Pathological Tissue Changes Associated With Polysubstance Toxicity: A Canadian Perspective

Janna M. Andronowski, PhD, Memorial University of Newfoundland, St. John's, Newfoundland and Labrador, Canada; Joshua T. Taylor, MS, Memorial University of Newfoundland, St. John's, Newfoundland and Labrador, Canada; Cindy Whitten, PhD, Department of Research & Innovation, NL Health Services, St. John's, Newfoundland and Labrador, Canada; Syed Raza, APM, Department of Research & Innovation, NL Health Services, St. John's, Newfoundland and Labrador, Canada; Shane Randell, MS, NL Health Services, St. John's, Newfoundland and Labrador, Canada; Nash Denic, MD, PhD, Forensic Pathology, Newfoundland and Labrador Health Services, St. John's, Newfoundland and Labrador, Canada*

Learning Objectives: The goals of this presentation are to: (1) describe how bone tissue pathology associated with polysubstance exposure is discernible in rib microarchitecture and may differ from opioid-only substance exposure, and (2) highlight the utility of a multimodal imaging approach including high-resolution Synchrotron Radiation-based micro-Computed Tomography (SRμCT) and traditional histology to characterize bone microstructural pathology associated with polysubstance exposure.

Impact Statement: This presentation will impact the forensic science community by disseminating novel research related to the effects of polysubstance exposure on bone microstructural integrity. As Canada's opioid epidemic worsened through COVID-19, and most opioid-related deaths involve substances from other classes (e.g., stimulants), it is critical that further research efforts be undertaken to understand the impacts on bone metabolism. Forensic anthropologists are specifically challenged by the confounding effects of substance exposure on fracture assessment and age-at-death estimation from bone tissue.

Abstract Text: Drug toxicity deaths continue to rise in Canada and are driven by polysubstance toxicity (i.e., exposure to multiple substances belonging to different drug classes). Recent literature and surveillance data suggest a shift from misuse of prescribed opiates to polysubstance toxicity, with stimulants involved in 70% of opioid deaths in 2024.[1-3]

The primary goal of this preliminary study was to describe how polysubstance exposure affects microscopic structures and overall porosity of cortical bone microarchitecture at a site commonly used in histological age-at-death estimation: the mid-shaft sixth rib. We hypothesized that: (1) cortical bone porosity in the polysubstance exposure group exceeds that of healthy controls, (2) the abundance and density of cortical bone's cellular spaces (e.g., osteocyte lacunae) vary between groups, and (3) histomorphological parameters (e.g., intracortical remodeling) vary between groups.

Skeletal samples were ethically procured at the Office of Chief Medical Examiner (St. Johns, NL) and age-matched (range 30-60 years of age at death) for known polysubstance exposure and controls. Cortical porosity and osteocyte lacunar parameters were visualized via SRμCT at the Canadian Light Source synchrotron facility. Cylindrical Volumes Of Interest (VOIs) were isolated from reconstructed cortical bone datasets via ORS Dragonfly software. Porous spaces and osteocyte lacunae were separated from high-density bone using a high-throughput deep learning segmentation workflow developed by the Andronowski Lab.[4] Variables included total VOI volume (TV), total canal volume within VOI (Ca.V), average canal diameter (Ca.Dm), total number of lacunae (N.Lc), and average lacunar volume (Lc.V). To determine lacunar density per mm3 (N.Lc/BV), bone Volume (BV) was calculated as TV minus Ca.V. Cortical porosity was calculated as Ca.V/TV. Maximum pore number and density in the polysubstance group (201 pores/mm^3) exceeded controls (100 pores/mm^3). Maximum pore diameter (3 mm) exceeded controls (0.8 mm). Maximum osteocyte lacunar density of the polysubstance group (35,609 lacunae/mm3) exceeded controls (27,866 lacunae/mm^3). Results suggest that polysubstance exposure may accelerate new and irregular pore accumulation. We further detected a concurrent increase in cellular density.

Mid-shaft bone blocks from rib specimens were embedded in methyl methacrylate via a validated Andronowski Lab protocol.[5] Transverse thin sections were procured using a Well Diamond Wire Saw. Cortical bone microstructure was visualized using a Zeiss AxioObserver Z.1 brightfield microscope with tiling stage. Cross-sectional images were acquired at 5x magnification and photomerged using Image Composite Editor (Microsoft). Intracortical remodeling was depressed following polysubstance exposure, compared to controls. This pattern was observed in the counts and population densities of osteon types (e.g., single- and double zonal) and cortical fraction of remodeled bone. Our results confirm our hypothesis that polysubstance exposure dysregulates bone remodeling and its microarchitectural products.

Our research represents the first examination of bone tissue from decedents with well-documented polysubstance exposure history via a multimodality approach (e.g., SRμCT, histology). In the face of rising toxicity and polysubstance deaths, our ongoing work further characterizes polysubstance exposure comorbidities such as osteoporosis. Results of our preliminary research have broader applications as they offer promise to identify risk factors for early-onset osteoporosis that have forensic and clinical applications for predicting and interpreting skeletal trauma.

A83 An Examination of How Skeletal Element and Microstructure Alter DNA Amplification in a Novel Environment

Shelby L. Saut, MA, California State University, Chico, Chico, CA; Ashley Kendell, PhD, California State University, Chico, Chico, CA; Beth Shook, PhD, California State University, Chico, Chico, CA*

Learning Objectives: After attending this presentation, attendees will be able to evaluate how the environment and bone biology influence the amplification of DNA postmortem. They will be able to identify the skeletal elements and microstructures that are the most suitable for successful DNA amplification.

Impact Statement: This presentation will influence the scientific community by highlighting the utility of long bones, teeth, and compact bone in the successful extraction and amplification of DNA. Additionally, it will offer a glimpse into how the environment may also play a role in the successful amplification of DNA.

Abstract Text: Disaster victim identification has long called for collaborative work between DNA analysts and forensic anthropologists in the selection of human bone samples for DNA analysis. Successful amplification of DNA from bone samples is in part influenced by the specific element selected as well as its microstructure. While there has been a multitude of research on specific elements and microstructures over the past 20 years, there has been little discussion of how the environment influences the degradation of bone and by extension, DNA.[1-4]

This research examined the relationship between skeletal element, microstructure, and allelic dropout in an environment type that has yet to be explored within published literature. Data from 124 cases represented by 132 bone samples collected between 2017 to 2019 were obtained from the Pima County Office of the Chief Medical Examiner in Tucson, AZ. The element (including class and specific type) as well as the specific microstructure sampled for DNA were noted as were the number of loci that were successfully amplified. This data was analyzed using Analysis of Variance (ANOVA) and *t*-tests. This research found that allelic dropout continues to be heavily influenced by the element and microstructure sampled. Additionally, results aligned with previous literature as long bones (μ=20.61/24 loci) and teeth (μ=18.67/24 loci) had the highest number of loci amplify for element type. Results from skeletal microstructure also aligned with previous literature as compact bone (μ=20.61/24 loci) had the highest number of loci amplify. The ultimate conclusion of this research is that while the environment plays a large role in decomposition, its influence wanes in regard to the successful amplification of DNA from bone samples. It seems that regardless of environment type, bone follows the same degradation pathway. Therefore, the skeletal elements and microstructures best suited for the successful extraction and amplification of DNA continue to be long bones, teeth, and compact bone.

A84 Estimating Multi-Residency From Bulk δ18O Enamel Carbonate Sampling

Thomas A. Delgado, MA, University of Utah, Salt Lake City, UT; Kirsten A. Verostick, PhD, University of Utah, Salt Lake City, UT; Gabriel Bowen, PhD, University of Utah, Salt Lake City, UT; Stephannie Covarrubias, MPH, University of Utah, Salt Lake City, UT; Chris Stantis, PhD, Southern Illinois University, Carbondale, IL*

Learning Objectives: After attending this presentation, attendees will have a better understanding on how living in multiple residences influences embodied oxygen isotope compositions and its impact on the forensic interpretation of δ18O values. An interpretive framework that allows for the estimation of multiple residencies from a single bulk enamel carbonate sample will also be introduced.

Impact Statement: This presentation will impact those who utilize stable isotope data to assist with forensic identifications. The framework presented here allows for analysts to better account for influences from human mobility when interpreting isotopic data and compare known lived history information postmortem isotopic compositions. As long-distance human mobility increases, there is a need for refined approaches in the interpretation of human-derived isotopic data. Additionally, forensic cases with confounding and/or inconclusive isotopic data could benefit from a reanalysis with these considerations.

Abstract Text: Identifying human skeletal remains is a continually challenging process that often relies on multiple lines of evidence (e.g., the biological profile, genetic analyses) for resolution. The past 20 years has seen a rise in multidisciplinary modes of forensic analysis with the incorporation of stable isotope analysis receiving substantial attention.[1] In particular, the analysis of oxygen isotope "delta" values ($\delta^{18}O$) in human dental enamel has become a well-established tool for estimating the geographic origin of unidentified human remains. This method is premised on the correlation between the isotopic composition of local drinking water and enamel formed by individuals residing in that region, which is mediated by the spatial distribution of $\delta^{18}O$.

Dental enamel serves as valuable analytical tissue due to its resistance to diagenetic effects, its correlation with environmental $\delta^{18}O$, and its temporally constrained formation period that is not subject to tissue turnover. As such, enamel provides valuable insights into residency patterns over the span of its formation; however, certain tooth types require several years for enamel to fully form. This elongated period of tissue formation complicates efforts to accurately interpret $\delta^{18}O$ for mobile individuals that imbibe water from multiple residences. Over the past several years, there has been an increase in long-distance moves with internal migration within the United States reaching over eight million people in 2022, underscoring a need for interpretive frameworks that consider the effect of movement during enamel development.[2]

This study explores the impact of residential mobility on bulk enamel carbonate $\delta^{18}O$ values using data from Project FIND-EM, which has developed a reference database of isotope δ values from third molars for individuals with well-documented residential histories during molar formation (ages 7 to 15 years).[3] Most individuals (n=43) had two listed residences during this period, with fewer living in three (n=6) or four (n=2) locations. Results show a clear detachment between the observed $\delta^{18}O$ values of mobile individuals and the expected $\delta^{18}O$ water values for their longest residence during molar formation (R^2=0.33). A simple mean of predicted $\delta^{18}O$ values across each residence allows for a first-order reconstruction of bulk $\delta^{18}O$ values (R^2=0.48); however, a time-weighted mean considering the duration of each residence yields a stronger relationship (R^2=0.55). The number of residences does not appear to substantially impact this trend, with similar correlations observed between those with two or three residences. Additionally, we show that a Bayesian inference approach can estimate geographic regions and residence durations needed to compose a particular $\delta^{18}O$ composition. These findings demonstrate the potential to identify and model residential mobility from a single bulk sample, laying the groundwork for future applications in forensic contexts where the $\delta^{18}O$ value measured for a tooth from an unknown decedent may be compared to residential patterns reported in a missing person record.

A85 Isotope Ratios in Paired Human Bone and Hair Samples for Forensic Applications

Tiffany B. Fracchia, PhD, Vanderbilt University, Nashville, TN; Gregory E. Berg, PhD, DPAA, JBPHH, HI; Lesley A. Chesson, MS, DPAA Laboratory, JBPHH, HI*

Learning Objectives: After attending this presentation, attendees will understand the relationship between stable carbon and nitrogen isotope ratios from paired samples of human hair and bone collagen. Attendees will also understand how human hair isotope datasets can be more reliably used to predict expected isotope values for bone collagen for the same population.

Impact Statement: This presentation will impact the forensic science community by providing a more robust dataset of carbon and nitrogen isotope values from paired human hair and bone samples from a population appropriate and comparable to contemporary forensic casework. This work updates and improves the utility of widely available hair isotope datasets to accurately predict bone collagen isotope values.

Abstract Text: Awareness of the utility of stable isotope analysis to assist with forensic identification of human remains has grown significantly in recent years. The stable isotope ratios of carbon (δ^{13}C values) and nitrogen (δ^{15}N values) provide information about an individual's diet, which can allow unknown individuals to be sorted by the type of plants and the amount of protein in their diet. Archaeological studies of ancient remains have leveraged stable isotope analyses over the years, but application of these methods in contemporary forensic contexts requires rigor and validation using samples from populations comparable to those in modern forensic casework.

While there are many published datasets of isotope values of human hair from contemporary populations around the world, there are far less data available for bone collagen. Prior understanding of the relationship between isotope values from bone and hair was limited to archaeological samples, small sample sizes, or non-human animal subjects such as mice. The most comprehensive study of paired human hair and bone samples is that of O'Connell and colleagues, undertaken over 20 years ago, using a total of eight paired samples of human bone and hair from United Kingdom residents.[1] This research expands that work with an initial sample size *(n*=20) that is more than twice as large and a planned total sample size (*n*= 32) of four times the published dataset of O'Connell et al. The data provide a comprehensive understanding for the transformation of hair isotope values to estimated bone collagen isotope values, using samples from individuals who are representative of a current United States population.

The paired human bone and hair samples were collected from the UTK Donated Skeletal Collection at the University of Tennessee, Knoxville, a contemporary skeletal collection of known individuals. Preliminary results from the first 20 individuals indicate that the difference for δ^{15}N values (2.12‰) is notably larger than that previously reported by O'Connell and colleagues (0.86‰). The difference observed for paired bone and hair samples is similar to the difference between the bone collagen average from Isolocate (11.76‰, *n*=240) and the hair average published by Hülsemann and colleagues (8.9‰, *n*=1022) (i.e., ~2.9‰).[2,3] This suggests that the current research provides a more robust method for calculating predicted δ^{15}N values of human bone collagen from existing hair datasets. In contrast, δ^{13}C values exhibited an average difference between bone and hair of 1.35‰, comparable to the findings of O'Connell et al. (1.41‰).

As our study continues to expand these preliminary data with additional analyses, we expect that results will continue to provide a deeper understanding of the relationship between the isotope δ values from paired human bone and hair samples and advance the goal of making widely available isotopic data from hair more useful for estimating bone collagen isotope values, expanding the potential for forensic identification applications.

A86 United States Tooth Enamel Oxygen Isoscapes for Human Identification

Gabriel Bowen, PhD, University of Utah, Salt Lake City, UT; Kirsten A. Verostick, PhD, University of Utah, Salt Lake City, UT; Gregory E. Berg, PhD, DPAA, JBPHH, HI; Lesley A. Chesson, MS, DPAA Laboratory, JBPHH, HI; Thomas A. Delgado, MA, University of Utah, Salt Lake City, UT; Chris Stantis, PhD, Southern Illinois University, Carbondale, IL*

Learning Objectives: Attendees of this presentation will learn to reconstruct geographic life history using oxygen stable isotopes in human tooth enamel. They will be introduced to a new community-accessible database documenting oxygen isotope composition (δ18O) values of tooth enamel carbonate from modern United States residents, a national map summarizing these data, and approaches for using these resources in human identification.

Impact Statement: The impact of the presentation will be the development of human capacity for the use of isotope technology in forensic casework. These capabilities will advance causes including the resolution of cold cases, humanitarian investigations, and identification of the remains of American service members lost in foreign conflicts.

Abstract Text: Stable isotope ratios in human body tissues vary geographically and are potentially useful in reconstructing life history and identifying unknown decedents. The oxygen isotope composition ($\delta^{18}O$ value) of tooth enamel carbonate is a promising target for this work due to its expected correlation with drinking water $\delta^{18}O$ values, but we lack a large, well-documented, standardized database of human tooth enamel $\delta^{18}O$ values as a foundation for forensic applications. Building such a database covering the contiguous United States is the goal of Project FIND-EM, a collaboration between the academic research community and the United States Defense POW/MIA Accounting Agency. Third molars have been collected from human donors through acquisitions from existing tooth and skeletal collections and contributions by living participants (University of Utah IRB 00139648). Life history information spanning the period of third molar formation was also obtained, and samples were prepared and analyzed using standardized, experimentally supported laboratory methods.

Sample collection has been successful but also highlights challenges inherent in developing large-scale human tissue isotope databases. Contributions from living participants have varied between geographic regions, producing low sample numbers in some regions (particularly those with low population density) and large numbers in locations served by highly engaged dental industry partners.

Despite this, samples from >600 individuals offer representative coverage across much of the contiguous United States. Measured $\delta^{18}O$ values of tooth enamel carbonate show strong, coherent spatial patterns that correlate well with known patterns of variation in tap water $\delta^{18}O$ values. Isoscape models for enamel carbonate developed using two methods (kriging and linear regression against tap water) show that the majority (~75%) of the observed variation in tooth enamel carbonate $\delta^{18}O$ values is predictable based on geographic location. However, both methods reveal substantial ($1\sigma = 1‰$) variability among different individuals living within the same area. This implies that non-spatial factors such as individual behavior and physiology or environmental heterogeneity contribute appreciably to enamel $\delta^{18}O$ values, limiting the precision of isoscape predictions to ±1‰ (1σ) placing bounds on the resolution of geographic assignments made using enamel carbonate $\delta^{18}O$ measurements.

A87 A Dual-Isotope Approach to Enhancing Isotopic Models for the Identification of Human Remains in North Carolina

Nicole Long, PhD, North Carolina State University, Cary, NC; Ethan Hyland, PhD, NC State University, Raleigh, NC*

Learning Objectives: Attendees will learn how Strontium ($^{87/86}Sr$) and oxygen ($\delta^{18}O$) isotopes can be used to estimate geographic origin in forensic anthropology using a refined dual-isotopic model at the state level. Methods for spatial analysis, model evaluation using known individuals, and the limitations and improvements of a refined model are addressed.

Impact Statement: This study will impact the forensic science community by demonstrating how to construct a refined, region-specific dual-isotope model from drinking water sources that improves geographic origin estimation of human remains.

Abstract Text: Strontium ($^{87/86}Sr$) and oxygen ($\delta^{18}O$) isotopes are valuable tools for estimating geographic origin in forensic anthropology. These isotopes provide information that is used to reconstruct past mobility and can help aid in the identification of unknown individuals by linking their biological tissues to specific geographic regions. However, their effectiveness depends on regionally refined, high-resolution models to use for this comparison. This study develops a refined dual-isotope isoscape for North Carolina by combining $^{87/86}Sr$ and $\delta^{18}O$ values from drinking water sources across the state. Both $^{87/86}Sr$ and $\delta^{18}O$ values demonstrated clustered spatial autocorrelation (Moran's I $^{87/86}Sr = 0.78$, $p < 0.05$; Moran's I $\delta^{18}O = 0.76$, $p < 0.05$).

Using Analysis of Variance (ANOVA), spatial interpolation revealed significant $^{87/86}Sr$ variation aligned with North Carolina's physiographic regions (Inner Coastal, Outer Coastal, Inner Piedmont, Outer Piedmont, and Blue Ridge; ($F(4, 218) = 61.76$, $p < 0.05$)). Using Pearson's correlation coefficient, the relationship between $\delta^{18}O$ values and elevation showed a significant negative correlation ($\delta^{18}O$ ($r = -0.63$, $n=456$, $p < 0.05$). The model was also tested using two individuals of known origin from forensic anthropological casework in North Carolina. The result of the bivariate probability density function and the 95% confidence threshold revealed a clear spatial concentration of high probability regions for each individual's origin in central North Carolina; however, it did not capture the true region of origin for either case. Local deviations, particularly in metropolitan areas with drinking water sources that differ from rural areas, limited assignment accuracy. Adjusting the model by removing these extraneous values correctly predicts the origin of one of the two cases.

These findings highlight the need for expanded datasets and the development of enamel-based isoscapes to improve predictive precision. This dual-isotope model is a critical step in enhancing forensic identification efforts in North Carolina and demonstrates the utility of integrated geochemical approaches in forensic anthropological casework.

A88 Reassociation of Commingled Tibiae and Tali Using Geometric Morphometrics

Nicole Wray, MS, Mercyhurst University, Erie, PA; Stephanie Melillo, PhD, Mercyhurst University, Erie, PA*

Learning Objectives: Attendees will understand how the usage of 3D models and Geometric Morphometrics (GM) can assist with the reassociation of commingled skeletal remains. This presentation discusses the attempt to pair elements across joints, specifically the tibia and the talus, but the method can be applied to other articulating elements.

Impact Statement: One of the core responsibilities of a forensic anthropologist is the identification and reassociation of human skeletal elements, especially in situations of mass graves, natural disasters, or the commingling of archaeological collections. There have been successful studies in pair-matching skeletal elements, but there cannot be a full reassociation of a human body without pairing across joints. There have been some successful studies that utilize osteometric methods to achieve this. Progressing toward using virtual anthropology methods could increase accessibility and objectivity.

Abstract Text: To combat the issue of commingled skeletal remains, researchers have developed methods to reassociate elements. Pair-matching methods, both osteometric and virtual, are reliable and successful in reassociating antimeres.[1,2] However, complete resolution of commingling requires matching across articulating joint surfaces—a more challenging task that has been explored by comparatively few studies.[3,4]

This study applies GM methods to quantify and describe morphological covariation between articulating surfaces of the talus and distal tibia. We developed a landmark protocol that combines fixed landmarks and "semilandmark" curves to quantify size and shape of both articular surfaces. The landmark data were superimposed, slid, and subjected to a Two-Block Partial Least-Squares (2B PLS) analysis. The 2B PLS is a statistical analysis that incorporates elements of regression and ordination. The results include correlation coefficients and a statistical model of covariation that can be used in a predictive capacity.

The secondary aim was to assess whether the articular surface morphology of one element could be used to predict its articulating match. This was accomplished using a permutation-based approach. For each individual in the sample, the talus landmark configuration served as statistical model input, and output consisted of predicted distal tibia shape. A multivariate distance measure called Riemann distance was then calculated to quantify the morphological disparity between the predicted tibia and the known match.[5,6] For context, the prediction-to-known-match distance was compared to a distribution of distances between predicted and non-matching tibiae. The 2B PLS-based reassociation method was considered successful if the prediction-to-known-match distance falls below the distribution of non-matches.

Our results reveal that talus and tibia articular shape covary with respect to: (1) width of the talar trochlea and mediolateral expansion of the distal tibia, and (2) height of the talus and medial malleolar length of the tibia. Our results further quantify covariation in overall shape, which is measured by the RV correlation coefficient in 2B PLS. Landmark data superimposed and scaled by centroid size measure differences in shape alone, and exhibited an RV of 0.34. Landmark data that were only superimposed but not scaled captured differences in both size and shape, and returned the highest RV at 0.55. In combination, the results suggest that covariation between the two surfaces is dominated by size. Although the 2B PLS was successful in quantifying and describing covariation in the tibia and talus, the covariation coefficients and our permutation analyses indicate that shape alone was insufficiently strong to make for a reliable predictive model.

While GM methods were not successful in predicting matches across the tibiotalar joint, this method may be useful to decide among potential matches, providing a statistical basis for excluding those that fall outside the observed match boundaries. We suggest the most practical application of this method would be after physical articulation in the lab.

In future studies, GM should be applied to other joint articulation surfaces to determine whether reassociation is achievable virtually, as well as including full surface data in addition to fixed landmarks and "semilandmarks."

A89 An Isotope-Aided Multifactorial Segregation of Skeletal Individuals From a Complex Small-Scale Commingled Assemblage

Janet E. Finlayson, PhD, DPAA, Joint Base Pearl Harbor-Hickam, HI; Gregory E. Berg, PhD, DPAA, JBPHH, HI; Rebecca J. Taylor, PhD, Defense POW/MIA Accounting Agency, kapolei, HI; Lesley A. Chesson, MS, DPAA Laboratory, JBPHH, HI*

Learning Objectives: The objective of this presentation is to highlight the utility of stable isotope analysis as part of a multifactorial approach for sorting commingled human remains via a small-scale, closed-population case study of highly commingled and poorly preserved skeletal elements.

Impact Statement: This presentation will impact the scientific community by demonstrating the importance of a multifactorial approach to resolving commingled cases with high complexity and how analysis of stable isotope ratios can increase segregation potential when traditional individuation means are unsuccessful.

Abstract Text: The complexity of commingled human remains cases increases as remains conditions declines, the number of individuals increases, and if the recovery circumstances are poorly known. Our agency frequently encounters such cases as a routine part of forensic casework. This case study discusses the approaches used to resolve commingling, highlighting the use of stable isotope analysis.

In 1944, a B-25C aircraft with six crewmembers was lost during a bombing raid on Meiktila, Burma; four were killed in the crash while two survived but were taken prisoner. Those killed were buried by local villagers in a single common grave and were later recovered in 1946. Initial analysis discovered commingling and the remains were reportedly sorted based on color, texture, size, articulation, and bone morphology into four individuals that could not be identified; they were eventually interred at a national cemetery in 1947 as four unknowns.

The remains were disinterred in 2022 in an effort to identify the individuals. The remains were highly fragmentary, poorly preserved, and commingled. Anthropological sorting primarily evaluated visual pair-matching, the fit of available reliable joint articulations, and refits of fragmentary elements, concluding with an estimated Minimum Number of Individuals (MNI) of four. Due to poor preservation, it was not possible to sort many skeletal elements—such as crania, vertebral columns, pelves, and some long bones—to a specific individual. Select skeletal elements were sampled for DNA analysis (N=29), yielding four distinct mitochondrial DNA (mtDNA) sequences and affected sorting additional elements, but nine elements failed to yield mtDNA results. To associate as many of the remaining skeletal elements (to include multiple crania) as possible to specific individuals, 31 elements underwent stable isotope analysis, 7 of which previously yielded mtDNA results; these latter isotope test results were used to build reference profiles of $\delta^{13}C$ and $\delta^{15}N$ values for each individual.

The measured $\delta^{13}C$ and $\delta^{15}N$ values of bone collagen from the tested elements were compared to published intraperson isotopic variation limits, also concluding with an MNI of four.[1] One distinct cluster of nine skeletal elements with notably high $\delta^{15}N$ values represented one individual; the remaining three individuals were represented by profiles of similar $\delta^{15}N$ values but differing $\delta^{13}C$ values, with some elements intermediate between profiles and unassigned to a specific individual. These indeterminate elements were easily associated to specific individuals via additional anthropological sorting, DNA associations, and exclusion. Though some skeletal elements have been documented with larger than expected error rates for sorting based on intraperson isotopic variation limits (e.g., crania, pelves), in this case, the crania and pelves sorted correctly isotopically and were confirmed via DNA and anthropological analyses.[1]

Sorting accuracy was shown by uniform biological profiles, consistency in perimortem trauma presentations within each individual, and dental matches/exclusions. This multifactorial approach to individuation using anthropological, isotopic, and DNA analyses resulted in representation of most skeletal regions for each case and promoted identification of the four individuals.

A90 Laser-Induced Breakdown Spectroscopy of Submerged Remains: The Implications for Their Re-Association in Commingled Situations

Matthieu Baudelet, PhD, University of Central Florida, Orlando, FL; Kristen M. Livingston, PhD, University of Central Florida, Orlando, FL; Gregory E. Berg, PhD, DPAA, JBPHH, HI; Lesley A. Chesson, MS, DPAA Laboratory, JBPHH, HI; John G. Lucchi, PhD, National Center for Forensic Science, Orlando, FL; John E. Byrd, PhD, DPAA, Mililani, HI*

Learning Objectives: This presentation will explain the effect of long-term submersion of skeletal remains on their elemental profile obtained by Laser-Induced Breakdown Spectroscopy (LIBS). The attendees will learn about the use of LIBS for the re-association of commingled remains and how their submersion influence the performance of the approach.

Impact Statement: LIBS is a demonstrated technique to be considered for the re-association of commingled remains. Its success for remains decomposed on ground surface and buried archeological to submerged remains makes it a serious addition to the forensic anthropology tool set.

Abstract Text: The re-association of commingled remains can be challenging, requiring time, lab space, and experience, especially when the bones are fragmented.[1] The use of chemical profiling may provide valuable information to support the sorting process. Several studies have shown that chemical variation exists between individuals' bones as a result of various factors, such as diet, health, and living environment.[2,3] LIBS is an elemental chemical analysis that relies on laser sampling of nanograms of a material to generate a micro-plasma emitting its elemental profile. It is portable, visually non-destructive, without extensive sample preparation, and can quantify low-Z elements such as carbon, hydrogen, nitrogen, and oxygen. These properties make it a strong complement to traditional X-ray fluorescence for field chemical analysis.

This presentation will show how the use of LIBS for reassociation has been developed using remains from 60 individuals that underwent surface decomposition, leading to an accuracy of 87% using supervised learning algorithms.[4,5] Following this simulated situation, we expanded the technique to submerged human remains from the Defense POW/MIA Accounting Agency. The difference from surface decomposition to marine conditions will be discussed, with confirmation from DNA results for identification. The reproducibility of the approach was also evaluated twice on a same case one year apart and showed similar high accuracy of 90%.

A parametric study performed in laboratory and field settings helps understanding the evolution of the elemental profile of bones once submerged in fresh and salt water. The LIBS profile is able to record the loss of collagen from the bones, and the exchange of elements between the bones and the water such as potassium and sodium leaching out while magnesium is being incorporated into the bone surface.

Elemental profiling using LIBS is shown to be helpful and reproducible to assist in the re-association of commingled remains, independently of the decomposition conditions of the remains. This provides a new tool for forensic anthropologists in order to complement their analysis with instrumentation that is easy to implement in a laboratory setting.

A91 Man's Best Friend: Multi-Species Commingling Resolution of Highly Fragmented, Canine-Scavenged Remains Using Zooarchaeology by Mass Spectrometry (ZooMS)

Andrea Palmiotto, PhD, Indiana University of Pennsylvania, Indiana, PA; Jerry L. Overman, Jr., Indiana County Coroner's Office, Indiana, PA; Emily J. Sykora, MA, Natural Resources Conservation Service, Hutchinson, KS; Anneke Janzen, PhD, Department of Anthropology, University of Tennessee, Knoxville, Knoxville, TN*

Learning Objectives: After attending this presentation, attendees will be aware of the value of collagen peptide mass fingerprinting methods of osseous identification for multi-species commingled assemblages and the impacts of canine scavenging on analysis.

Impact Statement: This presentation will impact the forensic science community by demonstrating the utility of an additional method to facilitate commingling resolution—collagen peptide mass fingerprinting. This presentation further shows how this method can reveal additional insight into the spatial distribution of scavenged remains using a case study of highly fragmented, canine-scavenged, multi-species commingled remains.

Abstract Text: In situations of multi-species commingling, resolution is typically achieved through visual identification of diagnostic bone markers, histological sampling, and/or genetic testing. However, when these methods cannot be utilized, forensic anthropologists must find other ways to distinguish human remains. Collagen peptide mass fingerprinting by Matrix-Assisted Laser Desorption/Ionization-Time-Of-Flight (MALDI-TOF) mass spectrometry, also known as Zooarchaeology by Mass Spectrometry (ZooMS), is a minimally destructive, cost effective, and time efficient means to taxonomically identify osseous remains.[1] ZooMS measures peptide mass spectra, emphasizing taxonomically informative marker peptides found in type I collagen. It has been used extensively in archaeological and paleoanthropological contexts but has not been prominent in forensic contexts.[2]

This western Pennsylvania case study incorporates ZooMS to assess the utility of collagen-based taxonomic identification for canine-scavenged remains. The decedent's remains were scavenged by more than 40 canines in a rural residential area over a two-week period and found commingled with identifiable non-human fauna, predominantly deer and dog. Portions of the decedent's skull and appendicular skeleton were identified. Most of the axial skeleton was not identified.

A team of volunteers systematically recovered over 2,000 osseous remains across the property, using gridded surface collection in the area with concentrated osseous remains and pedestrian survey in other areas of the site. Remains were recovered from the ground surface and from fecal matter. Fewer than 200 fragments could be identified visually to species. Most recovered fragments were too small or in too poor condition.

Subsequently, 30 canine-scavenged control samples were submitted for ZooMS analysis. This included samples from dry cow bones gnawed by domestic dogs for several hours (n=15) and canine-scavenged deer bones recovered from the decedent's residence (n=15). All samples yielded sufficient collagen for identification. Resulting mass spectra were visually assessed using mMass open-source software.[3] The deer samples had noisier spectra with higher m/z than the cow bones, which increased the difficulty of identification. However, only one sample (3%) was misidentified as canine.

Subsequently, 263 (12.3%) unknown, canine-scavenged samples were submitted for analysis. Twelve samples (n=12, 4.6%) were identified as human, nine of which were recovered from fecal matter. Most samples were identified as deer (n=171, 65%) and dog (n=46, 17.5%). Other specimens were broadly identified as bird and carnivore, as well as more specific identifications of turkey and rabbit (n=4, 1.5%). One sample (0.4%) included spectra indicative of both dog and deer and was interpreted as dog-digested deer tissue. Twenty-four samples failed (9%) and five samples (1.9%) did not have identifiable spectra.

These results are consistent with expectations based on visual identifications of larger bone portions. The ZooMS-identified human fragments clustered within the larger gridded area, indicating additional transportation of remains and possible area of consumption or waste deposition. Although the quantity of ZooMS-identified human remains could not account for the missing portions of the decedent, these outcomes indicate that collagen peptide mass fingerprint taxonomic identification methods offer effective means of resolving multi-species commingling in recent forensic cases where remains exhibit substantial canine scavenging.

A92 Investigating the Utility of Surgical Intervention Products for Personal Identification

Jered B. Cornelison, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; B E. Charles, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Christine M. Pink, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

Learning Objectives: Attendees will learn how various surgical interventions and implants can be used for personal identification in cases requiring a scientific identification. Attendees will also learn how to discriminate between interventions that may not constitute the basis for personal identification and those interventions that, based on their position relative to other features and idiosyncratic implantation methods, can constitute important personally identifying information. Attendees will learn the importance of understanding the surgical practices that result in radiographic variation of various materials.

Impact Statement: This presentation will impact the forensic community by drawing attention to the value of specific surgical materials for radiographic personal identification and the need for validation research on personal identification using radiographically visible surgical interventions often present in radiographic studies.

Abstract Text: Currently, the Academy Standards Board (ASB) standard for human identification states scientific identification is "the process of systematically comparing antemortem and postmortem biological data to facilitate a personal identification." Surgical products are manufactured on a large scale and used in numerous patients; therefore, the presence alone does not constitute a basis for personal identification. However, the relationship of surgical devices to adjacent human anatomy, variation in the placement of these products, and the inclusion of products related to a surgical procedure is individualizing. This survey of scientifically identified decedents explores the use of surgical interventions commonly observed in radiological studies as specific markers of personal identification. Specifically, this survey considers whether the presence, position, and morphology of these products can be studied in a stepwise class characteristic manner.

This survey of comparative medical radiographies accomplished at the Office of the Medical Examiner between 2014 and 2025 was conducted to evaluate whether certain surgical interventions could be used for personal identification. This study included 336 cases in which surgical interventions were used in the comparative medical radiography identification report. There was a total of 405 surgical interventions with 64 individuals exhibiting more than one intervention. The specific interventions included cruciate ligament repairs, cardiac valves, craniotomy hardware, hip arthroplasty, shoulder implants, knee implants, Inferior Vena Cava filters, orbital fixation, plate and screw fracture repairs, screw fracture repairs, radioactive prostate seeds, rod and nail fracture repairs, surgical staples/clips, rotator cuff repairs, spinal fusions/fixations, stents/mesh grafts, and sternotomy wires.

Although the presence and position of surgical products does not constitute the basis for personal identification alone, the morphology of the materials as it relates to the relative position of anatomy and bone healing; number, relative length, and variable angles of screws and plates; radiographic patterns of medicated cement used in the installation of implants; variability in number, shape, and twists of sternotomy wires; the number, position, and spatial relationship of multiple surgical staples, surgical clips, and prostate seeding; and the position and shape of stents and grafts likely constitutes personal identification. The observed variation is likely attributable to variable surgical training, surgical approach preference, individual anatomy, and personalized injury treatment.

Finally, the results of this survey demonstrate a need for forensic anthropologists to conduct validation research on the individuation of surgical products in forensic anthropology, including a basic understanding of the sources of variation that influence the placement and morphology of medical products.

A93 Personal Identification Through Comparative Medical Radiography: Guiding Training Through Recent Trends

B E. Charles, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Jered B. Cornelison, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Christine M. Pink, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

Learning Objectives: Attendees will learn about comparative medical radiography and recent patterns in personal identifications conducted by forensic anthropologists within an Office of the Medical Examiner. Anatomical regions of the body most relied upon for identification are highlighted, and common adaptations and challenges in comparative medical radiography are demonstrated through a series of case studies.

Impact Statement: This presentation will impact the forensic science community by guiding training and educational standards for this core competency in forensic anthropology. It will address biases in comparative medical radiographic identification toward certain regions of the body due to factors such as availability of antemortem imaging, quality of imaging, range of variation, and preservation of the remains.

Abstract Text: Forensic anthropologists are specialists in the human skeleton and recognize the range of variability in skeletal structures. Comparative Medical Radiography (CMR) is a core competency that forensic anthropologists use when other means of identification are unfeasible due to postmortem conditions such as decomposition, trauma, and thermal alteration.[1-3]

Radiographs and Computed Tomography (CT) scout images collapse overlapping three-dimensional anatomical structures into two dimensions and require education in radiographic skeletal anatomy beyond traditional osteology.[4] Forensic anthropologists must have a strong understanding of radiologic protocols for living patients and recognize that the protocols used to produce many antemortem images cannot be replicated in the postmortem environment. Adaptations for image production in the postmortem environment should be incorporated into CMR training and examples are illustrated in this paper. Experience in identifying explainable differences due to factors such as decompositional artifacts, positioning, magnification, distortion, and growth and developmental changes supplements radiologic training.

This presentation summarizes recent trends in personal identifications made through CMR at an Office of the Medical Examiner. A total of 1,484 scientific identification cases were completed between June 2014 and May 2025. Comparative medical radiography was used to identify 875 of those decedents; the remaining decedents were identified by fingerprint comparison (n=346), comparative dental radiography (n=164), DNA (n=34), and multiple corresponding factors or other identifying features (n=70).

The most frequently used anatomical region of interest as identified in antemortem imaging was the chest (n=362), followed by the head (n=288), cervical, thoracic, or lumbar spine (n=216), and abdomen (n=212). Two or more anatomical regions were included in comparisons for 512 cases. Specific elements most frequently used were thoracic (n=560) and lumbar (n=438) vertebrae and the frontal sinus (n=314). In 413 cases, both antemortem radiographs and CT imaging were available for comparison. These totals are consistent with results found by Flaherty and Byrnes and reiterate the importance of multimodal training with emphasis on the chest/thorax and the head and neck.[5] Education in radiographic anatomy, methods, and adaptations to the postmortem environment will support research to further develop and validate methods and strengthen the identification process. Future contributions to the growing body of CMR-related publications should include additional validation of methods, including statistical measures of uncertainty and specificity.

A94 Quantifying the Frontal Sinus to Improve Positive Identification Methods

Brailey Moeder, MS, University of Nevada, Reno, Reno, NV; Stephanie Melillo, PhD, Mercyhurst University, Erie, PA*

Learning Objectives: This presentation provides quantitative descriptions of human frontal sinus variation by analyzing imaging data. The audience will learn about a novel measurement protocol and computer programs used for sinus quantification. We address the gaps in current qualitative methods and discuss more standardized and replicable approaches that assess sinus morphology quantitatively.

Impact Statement: With the increased frequency of Computed Tomography (CT) data, practitioners will have the ability to improve methods of comparative identification, including the possibility of reporting expected error rates.

Abstract Text: Frontal sinus morphology has been reported to be just as individualizing as fingerprints.[1] Human variation is key to individualizing a person by their morphological features. The frontal sinus is a favored anatomical structure for radiographic comparisons, as it shows great individuality.[2,3] Although qualitative methods have been successful in identification efforts, researchers have identified the need for a protocol to standardize orientation and to quantify morphological observations.[2,4,5]

This study contributes to improving comparative identification methods by: (1) developing a sinus measurement protocol, and (2) quantifying morphological variation in the frontal sinus. The virtual dataset consisted of Computed Tomography (CT) scans (n = 50) from the New Mexico Decedent Image Database (NMDID). The scans were manipulated in freeware programs to collect craniometric landmarks and to generate standardized Three-Dimensional (3D) models. These datasets are measurements of sinus shape, size, and location used to describe biological variation.

Sinus size was quantified as the volume (mm^3) of the digital models. Size variation was explored with reference to a notoriously variable bone (the clavicle). The Coefficient of Variation (CV) was used to compare variation between the differently sized structures. We show that the frontal sinus is roughly three-fold more variable in size than the clavicle. Size is not dimorphically patterned in our sinus sample (t= 1.15, p>0.05), though clavicle size is highly dimorphic (t= 5.16, p< 0.001). Together, these results provide quantitative support for the idea that the sinus cavity is more variable than bones, likely due to the different developmental mechanisms responsible for generating the two skeletal structures.

We present a novel approach to compare sinuses between two CT scans, using frontal bone landmarks to standardize the position of sinus models in 3D space across individuals. To quantify shape similarity, we apply a model-to-model distance algorithm to the superimposed sinuses. The resulting distance values represent differences in both shape and location. By performing a pairwise comparison analysis, numerical non-match boundaries were calculated. The median distance between non-matches was 1.7 mm, with a range of 0.003–11.2 mm.

The extreme variability of the frontal sinus is obvious, but more specific information is still needed to fulfill *Daubert* guidelines. How similar can two sinuses look if they are from two different people? How different can the sinus of the same person look in two different CT scans? This study contributes to addressing the former question, while future studies incorporating additional data sources are needed to address the latter question.

A95 Anatomical Variants of the Skull: The Potential Use for Identification Purposes

Paolo Palermo, MD, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy; Sofia Alemanno, PGCert, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy; Carlo Pietro Campobasso, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy; Andrea Palamenghi, PhD, LABANOF (University of Milan); Department of Biomedical Sciences for Health (University of Milan), Milan, Lombardia, Italy; Giulia Caccia, PhD, LABANOF (University of Milan), Milan, Lombardia, Italy; Daniele Maria Gibelli, MD, PhD, Department of Biomedical Sciences for Health (University of Milan), Milan, Lombardia, Italy*

Learning Objectives: After attending this presentation, attendees will gain an understanding of anatomical variants of the skull, offering an insight into their potential for personal identification purposes.

Impact Statement: This study is set to share data provided by the analysis of cranial non-metric traits for identification purposes and explore thier frequencies and detectability both in skeletal collections and in Computed Tomography (CT) images.

Abstract Text: Anatomical variants are well known non-metric traits or epigenetic features morphologically assessable, widespread throughout the entire skeleton. The skull presents the widest array of traits that vary in morphology, number and frequencies across different population groups. Although these traits have been traditionally employed in bioarchaeological studies for interpopulation variability and kinship analyses, the possible use in personal identification as a secondary identifier has been suggested when the application of primary identification methods (fingerprints, dental records, and DNA) cannot be applied.[1-9] However, their full potential has not been entirely clarified yet. With this purpose, a research project has been designed and carried out by the University of Milan and University of Campania in Italy. The aim of this study is to assess the potential use of cranial non-metric traits for identification purposes and explore the detectability of non-metric traits in a skeletal collection and in CT images.

CT scans of 453 adult Italian individuals (185 females, 268 males), aged from 18 to 100 years, without traumatic or congenital cranial diseases, were analyzed. The frequencies of 24 non-metric traits (16 bilateral, 8 unpaired) were assessed. Thirty-seven adult skulls from an archaeological collection were also analyzed. Sex, population affinity, and frequencies of 39 cranial non-metric traits (30 bilateral, 9 unpaired) were assessed. Craniometric sex estimation identified 19 females (51.4%) and 18 males (48.6%). Twenty crania (54.1%) were classified as White and 6 (16.2%) as Black.

In the CT set, the lesser palatine foramina (95.8%), frontal sinus scalloping (94.9%), and the pharyngeal tubercle (93.3%) were the most frequent, whereas metopism (5.5%) and maxillary torus (9.9%) were the less common. In the archaeological sample, the most frequent traits included the mastoid foramen (92.0%), the pharyngeal tubercle (81.0%), and the supranasal suture (70.3%). The least frequent traits were the maxillary torus and the supraorbital foramen (both 5.0%). Some other traits like Inca bone, bipartite parietal bone, os japonicum, bipartite temporal squama, and metopic fissure were never observed.

The comparison of anatomical variants detected from the skeletal collection and from the CT scans shows that pharyngeal tubercle and minor palatine foramen can be easily recognizable both from the bone and the radiological imaging. Instead, the frontal sinus scalloping and the pneumatization of different skull areas can be detected only from CT scans. In particular, the pneumatization of crista galli was the less common variant (3.9%), while the pneumatization of the dorsum sellae was the most common (45.2%). Unfortunately, there is still a lack of information about the variation of most of the skull variants among different populations. Further studies on larger and more diverse collections, including other population groups, are needed. However, our preliminary results show that a combination of anatomical variants could significantly increase the potential of these traits as primary markers for personal identification.

A96 Drier Futures, Falling Waters: A Retrospective Analysis of Lake Mead's Forensic Anthropology Cases

Jennifer F. Byrnes, PhD, University of Nevada, Las Vegas, Las Vegas, NV; Liam Johnson, MA, University of Nevada, Las Vegas, Las Vegas, NV; Dayanira Lopez, MS, University of Nevada, Las Vegas, Las Vegas, NV; Melanie Rouse, MA, Clark County Office of the Coroner/Medical Examiner, Las Vegas, NV; Nathan Shaller, MD, Clark County Office of the Coroner/Medical Examiner, Las Vegas, NV*

Learning Objectives: After attending this presentation, attendees will understand how climate change in the form of extreme heat and aridity alters the landscape, revealing cases that are decades old and requiring the skillset of an anthropologist. Recommendations for revisiting our methods and expectations as practitioners will be discussed.

Impact Statement: This presentation will impact the forensic science community by demonstrating how climate change is affecting forensic anthropology casework patterns and, conversely, how forensic anthropologists can provide information that can aid medicolegal stakeholders in their investigations by providing more accurate estimates of time since death, improving chances of identification, and promoting interagency collaboration.

Abstract Text: Aridification driven by anthropogenic climate change has reduced runoff across the Colorado River Basin and lowered Lake Mead's water volume by more than 150 feet since 2000. Lake Mead, located on the state borders of Nevada and Arizona, provides fresh water to much of the southwestern United States. The Colorado River contributes 97% of the lake's water and flows westward under the lake's surface. The lake hydrodynamics and thermally stratified water column dictate how decedents' remains are transported from their death location. Climate modeling predicts continued aridification, with Clark County's mean temperature projected to rise by 5-10 degrees by 2100. As lake levels continue to fall due to diminished snowpack, increased evaporation, and prolonged drought, exposure of human remains presents opportunities and challenges for forensic anthropologists.

This study explored how skeletonized cases in an aqueous setting present challenges for forensic anthropologists and their collaborators. Using the Clark County Office of the Coroner/Medical Examiner's database, the parameters to identify cases were: (1) medicolegal cases found in/adjacent to Lake Mead; and (2) had a forensic anthropology report. Of 248 cases, ten met these parameters. Eight have been identified, representing five people; three were consolidated once identifications were confirmed. Two cases—recovered in 2022 and 2007—remain unresolved. Over half were discovered in 2022 when the lake reached its lowest pool elevation (1,040 feet) since 1937, when the reservoir was created.

For identified cases, the actual Postmortem Interval (PMI)—from the last known alive dates to discovery—was compared against Postmortem Submersion Interval (PMSI) estimates derived from Heaton and colleagues' Total Aquatic Decomposition Score (TADS) method.[1,2] The biological profile and taphonomic observations were used for unidentified cases. Spatial data were mapped to display the distribution of the last-seen recovery location and/or the death scene. The identified decedents' last known alive dates and unidentified cases' material evidence *terminus post quem* dates range from the 1970s to the early 2000s. The demographics of identified decedents were White males ranging in age from 26 to 52. Manner of death was undetermined for most cases (71.4%); one case was a homicide, and another an accidental drowning. Approximately 70% of the cases have been identified.

All aqueous cases evaluated following Heaton and colleagues' underestimated the PMSI.[2] Gross (visual) PMSI methods are not well-suited for long-term skeletonized or saponified cases; yet, more submerged cases are likely to be revealed. Bioerosion, abrasion, encrustation, and dissolution are diagenetic processes that assess PMSI in completely skeletonized remains. However, these typically require specialized and/or destructive sampling. Thus, there is a need for PMSI studies in general, and specifically as they relate to skeletonized cases. Improving PMSI methods and documenting spatial displacement will enhance the forensic anthropologist's ability to reconstruct timelines, assist identification efforts, and support investigators in identifying decedents. Coroners and medical examiners face unique challenges due to climate change uncovering decades-old cases, including difficulties in identifying decedents and determining their cause and manner of death. This discovery simultaneously presents opportunities to compare these long-term cold cases with missing persons reports.

A97 Wildfire Deployment: Lessons From the California Wildfires

Alison Galloway, PhD, UC Santa Cruz, Volcano, CA; Chelsey A. Juarez, PhD, California State University Fresno, Fresno, CA; Elayne J. Pope, PhD, Fatal Fire Research and Education, Knoxville, TN*

Learning Objectives: This presentation will prepare forensic anthropologists for deployment at wildfire mass disasters and scenes involving fire fatalities. It introduces how emergency field operation agencies should be aware of the forensic anthropologist's skillsets and professional services, how deployment is activated, what questions to ask before deploying, what types of Personal Protective Equipment (PPE) to bring, what supplies are provided, and how to document activities from field recoveries involving burned human remains.

Impact Statement: This presentation will provide realistic expectations for deployment to wildfire mass disasters and fatal fire scenes, field preparedness, maximizing the effectiveness of victim recovery and decreasing unnecessary concerns among forensic anthropologists and other non-agency-related experts during fieldwork.

Abstract Text: Deployment to multiple California wildfires drives home the importance of managing expectations in the field to minimize the physical and emotional burden so forensic anthropologists and forensic professionals can remain effective. Since we do not fit within the usual categories of mutual aid among governmental agencies (fire services and law enforcement), deployment is often a "black box" for the forensic anthropologist. Agencies will not automatically contact forensic anthropologists unless prior arrangements are made.

It is important to understand the expected responsibilities of the forensic expert—involving searches with Urban Search And Rescue/Search And Rescue (USAR/SAR) teams, recovering remains located by such teams, analyzing remains alongside the pathologists, or simply assessing remains (human/non-human) via images.[1-3] Based upon this information, we determine what equipment to bring.

One relatively consistent need is "just-in-time" training for the search teams. This training reviews how bodies will typically appear in the open, inside vehicles, and structures.[4] Educating searchers on orthopedic devices is important (hip, knee, and shoulder replacements) since many victims are older or disabled. They should be familiar with the most common items of confusion (burned plastics, curved drywall).

Instructions should cover search techniques. In most wildfires in rural areas, perimeter searches of burned structures are sufficient. Most bodies are found in bathrooms and bedrooms; however, local conditions can change. If people exit houses through a kitchen to get to a carport, their bodies may be in the kitchen. The Los Angeles fires also introduced the difficulty of searching extremely large, multi-storied homes that have completely collapsed. These scenes will require excavators, drones, and SAR dogs before searchers can safely enter. Flexibility in approach is essential.

Deployment conditions can involve tent camping, rustic conditions, barracks, or sleeping trailers. Privacy is limited. However, at the base camps, trailer facilities (showers and laundry) are usually available. Meals are usually on hand for breakfast and dinner, whereas lunches need appropriation prior to daily departures. Some expense, such as hotels may or may not be reimbursed. Alternative housing may be extremely limited due to the displacement of residents of the evacuated areas.

Daily activity logs are often required but may be requested months after the incident when reimbursements for mutual aid are distributed. These records also show the value of having forensic anthropologists in the field. Daily logs should include locations visited, number of cases viewed, and miles traveled.

Deployment into a fire zone comes with many hazards. Protective clothing, including hard-soled boots, helmets, and PPE, are essential but may not be available onsite for the initial deployment. Fit-tested respirators are essential in most fire scenes from exposure to heavy toxic smoke and volatile vapors from fire debris. Fire scene deployment also introduces potential emotional toll on those locating and recovering the victims. Bodies are often positioned as people who took refuge, tried desperately to flee or accepted their fate. Locations and circumstances are evident during recovery and bring home the terror the victims faced before their deaths.

A98 The Impact of Climate Change on the Mortality of Migrants: Forensic Casework in the United States Southwest

Jasmine R. Hernandez, MS, University of New Mexico, Albuquerque, NM; Lexi O'Donnell, PhD, University of New Mexico Health Sciences Center, Albuquerque, AZ; Heather Edgar, PhD, University of New Mexico, Albuquerque, NM; Daniel E. Martinez, PhD, University of Arizona, Tucson, AZ; Laura B. Nellums, PhD, University of New Mexico, Albuquerque, NM*

Learning Objectives: After attending this presentation, attendees will better understand the geographic distribution of migrant deaths in Arizona and New Mexico from 2000–2024, the leading causes of death determined by the forensic pathologists for such cases, and the role that warming temperatures in these areas have on the trends. They will also gain insight into how migration-related push and pull factors, shaped by social and political drivers, shape these patterns.

Impact Statement: This presentation will impact the forensic science community by highlighting how broader social, political, and climate-related factors can influence case patterns and how medical investigation systems can use this awareness to anticipate and adapt to changing trends in their caseloads.

Abstract Text: Human migration is a complex process driven by intersecting social, political, and environmental forces. Migration across the United States Southwestern border is predominantly undertaken by individuals from Latin America and is often shaped by increasingly restrictive policies, prompting migrants to cross through remote desert terrain where exposure to extreme heat can be fatal.[1] This study investigates the relationship between rising summer temperatures and migrant mortality in Arizona and New Mexico from 2000 to 2024.

We use data from Human Borders' Migrant Mortality Map, which includes cases primarily investigated by the Pima County Office of the Medical Examiner (PCOME), and data from the Office of the Medical Investigator (OMI) in New Mexico.[2] Temperature data from the National Oceanic and Atmospheric Administration (NOAA), including average, minimum, and maximum temperatures, were gathered by county for the summer months (June, July, August), which correspond to the period of highest migrant deaths in both states.[3]

Linear regression models and correlation analyses were used to evaluate whether summer temperatures have significantly increased over time and whether temperature predicts the number or cause of migrant deaths. Regression models treated migrant deaths as the dependent variable and temperature measures as independent variables. All models included year as a covariate. Linear regression models estimated that minimum, maximum, and average summer temperatures significantly increased across most counties in Arizona and New Mexico ($p < 0.05$), with predicted rates of temperature increase ranging from 0.05°F to 0.14°F per year. Positive associations were identified between rising temperatures and migrant mortality. The strongest observed correlation was in Pima County, AZ, where June maximum temperatures correlated at 0.61 with migrant deaths over the study period. Regression models also showed that migrant deaths increased with rising temperatures, with estimated increases ranging from 0.1 to 5.3 deaths per 1°F of temperature rise. Causes of death classified as heat-related or environmental exposure-related increased were combined due to sample size limitations and their shared association with extreme heat. This combined category increased in frequency as temperatures rose. Regression models showed that heat-related deaths increased with temperature, with estimated effects ranging from 0.2 to 5.7 additional deaths per 1°F of warming. Deaths classified as "undetermined" or "other" also showed significant associations with temperature increases. While "undetermined" cases often involve skeletal remains where specific environmental causes cannot be confirmed, they may nonetheless reflect exposure-related deaths. The "other" category encompasses a variety of causes, some of which may also be environmentally influenced.

Previous work connecting migration and climate change has largely focused on the latter as a push factor driving migration.[4] This study, however, highlights the growing relevance of environmental factors in medicolegal investigations of migrant deaths and the preventable consequences of unauthorized border crossings. While climate change appears to be associated with increased mortality, particularly among already vulnerable populations, it should be understood as one contributing factor among many. Political, economic, and structural inequalities, both in migrants' countries of origin and at the United States border, also play critical roles in shaping the risks migrants face.[4,5]

A99 Climate Change and Mass Disasters: The Role of Forensic Anthropology Outreach in Helping Communities Better Prepare for Mass Disasters

Colleen Milligan, PhD, California State University, Chico, Chico, CA; Eric J. Bartelink, PhD, California State University, Chico, Chico, CA; Ashley Kendell, PhD, California State University, Chico, Chico, CA; Shannon Clinkinbeard, MA, California State University, Chico, Lincoln, CA; Amber Plemons, PhD, California State University, Chico, Chico, CA*

Learning Objectives: After attending this presentation, attendees will learn about the role that climate change plays in the increasing frequency of California's wildfires and how that impacts the traditional role of the forensic anthropologist in scene recovery of fatal fire victims. In particular, the need for increasing the number of personnel trained to respond to the aftermath and recovery process will be discussed.

Impact Statement: This presentation will impact the forensic science community by demonstrating the importance of professional outreach as an expansion of the traditional roles forensic practitioners play in mass disasters. The increased frequency and scale of destructive wildfires mean that more responders are needed annually. Developing a network of trained responders in wildfire search and recovery is critical for efficient and effective search and recovery of remains of fire victims in mass fatality incidents.

Abstract Text: The California Department of Forestry and Fire Protection (Cal Fire) maintains active and publicly available statistics from 1932 to the present on the most destructive (combined structure loss and lives lost) fires in state history. Eighteen of the top 20 most destructive wildfires in California history have occurred since 2000, with eight occurring between 2020 and 2025 alone.[1] These data are correlated with available climate data in California from 2000 to 2024, which has been the warmest and driest period in the last millennium.[2] Like most of the Southwest, California's increasingly warm and dry conditions have led to decades of extended drought, frequently referred to as the "megadrought" era. These environmental conditions directly contribute to the increased destructiveness and frequency of wildfires in the state.[2]

The Human Identification Lab (HIL) at California State University, Chico, has deployed to wildfires on a near-annual basis since 2015. Traditionally, forensic anthropologists assist in recovery efforts, aiding in locating and identifying fatalities. The increased frequency of deployments and fatalities has led the HIL to become heavily involved in talks with state officials to improve future operations, using feedback from lessons learned. That role has included developing training courses for first responders and disseminating demographic and geospatial data about wildfire victims.

In partnership with the California Office of Emergency Services (Cal OES), the HIL has focused on increasing the annual training for civilian search and rescue workers, law enforcement personnel, and coroner investigators. Semi-annual wildfire courses consist of a one-day workshop with morning lectures on best practices for recovery of human remains, followed by a series of field exercises simulating the search for human remains in a burned environment. Participants are taught best practices for searching within burned structures, whereby searchers remain outside the structure's footprint. Between 2023 and 2025, data were collected from 150 course participants to examine the association between the order of field exercises and participants' abilities to locate human remains at varying distances up to 20 feet away from a structure's perimeter. The relationship between the order in which the field exercises were performed and the distance at which searchers could accurately identify remains approached significance (χ^2=8.747, df=4, p=0.068) and also showed a moderate, positive association ($\Gamma(y)$=0.319, p=0.002; τb=0.215, p=0.002). Thus, participants who completed at least one of the other field exercises before rotating to the test exercise were more likely to be able to spot human remains from a greater distance compared to those who started with the test exercise.

The results demonstrate that combining lectures with field training leads to faster and less destructive detection of remains by the searcher than lectures alone. A forensic anthropologist's ability to locate, identify, and aid in the release of remains to families affected by the disaster is directly impacted by the training received by all searchers. The faster and less destructive the initial field search is, the timelier the identification and release of remains can be.

A100 Scavengers on the Move: Geospatial Evidence of Changing Vulture Behavior in Forensic Landscapes

Lauren R. Pharr-Parks, PhD, Pharr Forensic Consulting, LLC, Memphis, TN*

Learning Objectives: After attending this presentation, attendees will understand how Global Positioning Systems (GPS), Geographic Information Systems (GIS), and remote sensing technologies were used to document changes in vulture flight patterns, travel distances, and roosting behavior—key factors in forensic anthropology and outdoor death investigations. Notably, results indicate that turkey vultures fly nearly three times faster, five times farther, and five times higher than black vultures, which may alter expected scavenging patterns. This new evidence significantly deviates from vulture behavior reported in a foundational 1989 radio telemetry study, highlighting the need for updated forensic models that account for shifting animal behavior in a changing climate.[1]

Impact Statement: This presentation will impact the forensic community by introducing a methodology that uses geospatial technologies to track vulture movement and behavior over time, revealing non-random flight patterns and significant species-specific differences in range and altitude.

Abstract Text: Vultures are critical accelerators of decomposition and can rapidly deflesh human remains, making their behavior highly relevant in outdoor forensic investigations. While previous research has focused on the physical effects of vulture scavenging on bone, less attention has been paid to long-term changes in their migration routes, foraging patterns, and scavenging territories in response to climate change and urban development.

To investigate these behavioral shifts, six vultures were trapped at Texas State Forensic Anthropology Research Facility (FARF), fitted with 70-g solar-powered GPS transmitters, and released on April 10, 2013. The sample included two adult turkey vultures (*Cathartes aura*), two adult black vultures (*Coragyps atratus*), and two subadult black vultures. The GPS transmitters collected hourly data for 19 hours a day over six months, generating more than 15,000 data points. Each data point recorded location, altitude, flight speed, direction, and a timestamp, with spatial and vertical accuracies of ±18 meters and ±22 meters, respectively.

Geospatial analysis within a GIS environment revealed that vultures traveled across large areas of Texas and into Oklahoma, yet FARF consistently remained the geographic center of their movement patterns. Roosting locations (N=841) were identified, and sequential distances between them were used to calculate daily travel ranges. The four black vultures traveled an average of 4,865.5 meters per day. In contrast, one turkey vulture traveled 5.4 times farther, and the other flew 7 times farther than the black vultures. Both turkey vultures exceeded the 15-kilometer daily range reported in the 1989 study by Coleman and Fraser, with no missing roost data.[1]

Spatial statistical tools, including mean center, median center, central feature, standard distance deviation, and standard deviational ellipse, were used to analyze roost distribution. Black vultures primarily followed the I-35 urban corridor, linking San Antonio, San Marcos, and Austin—suggesting a reliance on anthropogenic food sources. Turkey vultures, by contrast, roosted in more rural, dispersed areas. Despite these differences, three black vultures and one turkey vulture had roosting centers that overlapped closely, indicating shared core territories.

Nearest Neighbor Analysis (NNA) revealed that all six vultures had roosting patterns that were nearly perfectly clustered ($p < 0.001$), suggesting purposeful energy-efficient behavior rather than random distribution. These spatial dynamics provide valuable insights into vulture ecology that have forensic significance when determining postmortem intervals and interpreting scavenging activity.

This research demonstrates that vulture behavior changed significantly between 1989 and 2013. Turkey vultures in this study flew farther, faster, and higher than previously documented, likely due to changes in carrion availability, habitat loss, and climate-driven shifts in food distribution. Black vultures have adapted by remaining in urbanized areas and utilizing human food waste. Understanding these behavioral shifts is critical for modern forensic anthropology. If not recognized, changes in vulture behavior may lead to missed or misinterpreted evidence in outdoor death investigations. This research underscores the importance of integrating animal migration studies with forensic science to better assess postmortem intervals in a rapidly changing environment.

A101 Climate Change, Vulnerability, and the 2023 Lahaina Fire Victims' Locations and Demography

Patrick S. Willey, PhD, Chico State, Chico, CA; Casey A. Hegel, MA, Northeast Information Center, Chico State, Chico, CA*

Learning Objectives: By attending this presentation, attendees will learn how climate change altered Lahaina's environment, most importantly the weather and vegetation. These changes exacerbated conditions leading to the devastating 2023 fire that killed at least 102 people. Combining demography, locations, and social backgrounds of the victims, we demonstrate the impact that climate change had on who died in the Lahaina Fire.

Impact Statement: Hearing this presentation will impact the attendees' understanding of the interrelationships of climate change and the Lahaina Fire victims' demographic, location, and social vulnerabilities. They will learn how climate change altered the environment and made some demographic groups and certain locations more at risk. When similar catastrophes occur elsewhere, practitioners will understand what groups constitute the most vulnerable members of society, and what locations are most dangerous. These conclusions will aid emergency workers and searchers in understanding the magnitude, demography, and locations most affected by wildfires.

Abstract Text: Climate change affects weather and alters vegetation, in some cases, intensifying conditions conducive to wildfires and other natural disasters. Shifting weather conditions and more fire-prone vegetation united to produce the 2023 combustion on Maui, most notably the lethal Lahaina Fire. With fatalities reaching at least 102, the Lahaina Fire became the deadliest natural disaster during Hawaii's statehood.

As temperatures increase globally, ocean temperatures have also risen, consequently altering wet-dry cycles and increasing drought severity. Climate change appears to be causing hurricanes to become increasingly severe and slowing their travel speed. Additionally, as land uses change, non-native plants with increased flammability dominate some landscapes.[1]

At Lahaina, HI, climate change, weather conditions, plant flammability, social hierarchy, and colonial history collided in August 2023. Hurricane Dora, which passed hundreds of miles south of Lahaina, produced strong winds on the Islands. Those winds downed power lines and trees, and when dry vegetation ignited, the strong winds pushed the fire downslope, coastward, and through the town of Lahaina. As with other catastrophic events, the Lahaina Fire disproportionately affected particular segments of the Lahaina population, some socio-economic groups, and certain locations in the town, making those individuals more vulnerable to injury and some locations more dangerous.

The Lahaina demographic data comes from published records documenting the victims' ages and sexes, which are compared with information from the 2020 Lahaina census.[2-4] To evaluate the Lahaina victims' locations, 2018-2022 American Community Survey and 2020 decennial census data are analyzed with ArcGIS Pro and SPSS.[5]

Demographic assessments consist of age and sex. The fatalities' age distribution proves statistically different from the Lahaina 2020 census age distribution (K-S $D = 0.55$, $P_{0.01} = 0.162$). Victims over 65 years are particularly overrepresented (61.7%) when compared to that age group in the census (14.9%). A similar pattern—an overabundance of elderly fatalities—occurs in both sexes (females K-S $D = 0.58$, $P_{0.01} = 0.255$; males K-S $D = 0.53$, $P_{0.01} = 0.21$). In the Lahaina census, females (51%) slightly outnumber males (49%), but among the fatalities, the reverse occurs. Males (59%) outnumber females (41%, binomial $p = 0.0107$). As a final demographic consideration, no statistical difference in fatalities' ages occur between the sexes ($t = 1.139$, $df = 100$, $p = 0.065$).

The victims cluster spatially (Moran's I, z-score > 2.58, $p = 0.01$). There is a statistically significant relationship between the number of fatalities and population density ($r = .258$, $p = 0.001$). Victims tended to die in the central part of Lahaina. Most spatial clusters of fatalities occur among related victims, with at least 35% of the victims being related to another close-by victim. Evacuation behavior is often influenced by interpersonal relationships, as well as perceived risk and the ability to evacuate.

In conclusion, this presentation lies at the intersections of climate change, vulnerability, demography, and spatial locations. When similar climate change-related disasters occur, individuals disproportionately impacted will be the elderly, males, related groups, socially disadvantaged individuals, and those in dangerous locations.

A102 The Geography of Forensic Absence: Climate, Natural Disasters, and the Search for Unidentified Persons in Louisiana

Teresa V. Wilson, PhD, Louisiana State University, Baton Rouge, LA; Sara O. Finn, MA, East Baton Rouge Parish Coroner's Office, Denham Springs, LA*

Learning Objectives: After attending this presentation, attendees will understand how climate change and natural disasters produce forensic absence, which complicates efforts to locate and identify unidentified persons. They will also have a framework for countermapping that combines archival research and field techniques to address the challenges of cold cases.

Impact Statement: This presentation will impact the forensic science community by demonstrating a practical and interdisciplinary approach to recovering lost unidentified persons whose burial sites have been obscured by environmental change and historical neglect. It will also highlight the value of multi-agency collaboration, local knowledge, and anthropological methods.

Abstract Text: Hurricanes, major flooding events, sea level rise, and periods of intense drought have reshaped the landscape and practice of cold case forensic anthropology in southeast Louisiana. The state averages one hurricane every three years, while some years have more activity and devastating rare weather events. Most notably, Hurricane Katrina made landfall in 2005 as one of the deadliest hurricanes in history, and the 2016 Flood that dumped half (~30 inches) of the average amount of precipitation (~61 inches) in three days. These weather events are just a small example of how natural disasters, and the continuous effects of climate change, have disrupted cemeteries, erased physical records, displaced gravesites, and disrupted efforts to identify unknown decedents. This presentation explores the concept of *forensic absence*: a condition where unidentified persons remain unseen and nameless because the evidence needed to find them has been lost or rendered illegible. Ultimately, this case study asks the question: How can unidentified persons be located and identified when environmental change and record loss have left them invisible?

A joint project between the Louisiana State University Forensic Anthropology and Computer Enhancement Services (LSU FACES) Laboratory and the East Baton Rouge Parish Coroner's Office illustrates the challenges and potential responses to complex cases of forensic absence. The project focused on locating two unidentified persons in Magnolia Cemetery in Baton Rouge, LA. Between 1970 and 1990, these individuals were recovered in advanced states of decomposition from the banks of the Mississippi River, ultimately received insufficient investigative attention, and were lost within the records. It has been learned that cold cases from this time period have incomplete documentation and are especially vulnerable to layered absences. This presentation tracks the efforts to solve these cases and the difficulties encountered when erosion gradually erases gravesites, hurricanes strip away vegetation that once served as landmarks, and cemetery records disappear as communities are displaced.

To address these challenges, the project employed *countermapping*, which is a process of reconstructing space, memory, and data. Countermapping challenges the invisibility created by forensic absence, piecing together dispersed information to reconstruct lost burials and restore agency to the unidentified. This project reconstructed burial locations by employing a combination of stake-holder memory, archival fragments, ground-penetrating radar (GPR), historical aerial photographs, and systematic field surveys. Situation-specific countermapping recognizes that recovering unmarked burials requires multi-agency and community-engaged strategies. The successful recovery of both individuals required different but complementary strategies that highlight how forensic anthropologists can respond to changing physical and social landscapes. By tracing the geography of forensic absence, this work reframes climate change as both a present crisis and a historical force that continues to shape the possibilities of identification and justice.

A103 A Cold Case Reanalysis Demonstrates the Importance of Forensic Anthropology Training in the Interpretation of Trauma to the Skeleton

Ella Uren, BS, University of Indianapolis Human Biology Program, Indianapolis, IN; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN*

Learning Objectives: After viewing this presentation, attendees will understand the importance of specialized training in interpreting perimortem and postmortem modification to human skeletal remains in forensic casework. It will demonstrate how analytical errors can have dramatic impacts on the subsequent investigation.

Impact Statement: This presentation will impact the forensic community by emphasizing that the fundamentals of forensic science begin with solid training. In this case, a rigorous foundation in the interpretation of skeletal modifications is essential when providing consultation services to the medicolegal community.

Abstract Text: A cold case is an unsolved investigation that is not actively being pursued due to a lack of evidence or investigative leads. In forensic anthropology, this often means skeletonized human remains that have gone for many years without a positive identification. The University of Indianapolis Human Identification Center (HIC) and Identify Indiana Initiative, working with the Indiana State Police Cold Case Unit, has taken custody of a large number of human skeletal remains from another institution in the state of Indiana to reanalyze utilizing updated analytical and identification techniques. The cases predate consultations provided by the first board-certified forensic anthropologist in the state starting in 1991 and will benefit from updated techniques such as isotopic analysis, missing persons databases, and modern DNA technology. The ultimate goal is positive identification.

Several challenges were immediately recognized, including commingling due to use of the skeletal remains in classroom settings and a lack of paperwork and documentation resulting in the inability to properly associate cases with their investigative agencies. One case highlights another complication for ongoing investigation. For this case, the HIC submitted a report including the biological profile and descriptions of carnivore scavenging to multiple skeletal elements, indicated by the presence of tooth puncture marks, U-shaped scoring channels from tooth scraping, and bone loss at the ends of long bones with irregular fracture margins. Additionally, avian scavenging was observed in the eye orbits. Unbeknown to the HIC, an original case report did exist for this particular case, and it had caught the attention of the new investigators. The original report attributed the skeletal modifications to chainsaw dismemberment and the damage to the orbits attributed to a blunt-pointed implement.

Chainsaw cuts, or saw marks in general, typically display a square-shaped channel with a uniform kerf wall at the site of dismemberment. Secondary features like exit chipping, break-away spurs, and kerf wall striations can further corroborate the classification of a traumatic event as being caused by a saw. Carnivore damage leaves different and distinctive marks on the bone and indicates the individual was in an area that could be accessed by carnivores during the perimortem interval. Chainsaw dismemberment, on the other hand, indicates a criminal act by another party to dispose of the body or hinder the identification process. Inaccurate trauma analysis like this has a dramatic impact on the investigative process.

This presentation highlights the importance of training and modern trauma knowledge when analyzing forensic cases to prevent a misclassification of the skeletal modifications observed on the bone. It will discuss the differences between saw and carnivore modifications to bone and allow attendees to view the damage to the skeletal remains. In this case, the reanalysis done by the HIC demonstrates the modifications are due to postmortem scavenging and not nefarious. Positive identification is being pursued through forensic investigative genetic genealogy. A solid foundation in osteology training and knowledge of best practices in the field are the basic fundamentals of forensic science that uphold the rigor required of practice in the field.[1-7]

A104 Identification Patterns in Operation Identification Cases

Emma M. Giacomello, MA, Texas State University, San Marcos, TX; Michelle D. Hamilton, PhD, Texas State University, San Marcos, TX; Kate Spradley, PhD, Forensic Anthropology Center at Texas State University, San Marcos, TX*

Learning Objectives: Attendees will gain insight into how secondary identifiers contribute to identification hypotheses and timelines of identification for migrant decedents. This research underscores the utility of secondary identifiers in forensic humanitarian work and supports their use when primary identification methods are not available.

Impact Statement: This research emphasizes the importance of secondary identifiers in the identification of migrants, especially when primary methods of identification are delayed or unavailable. These findings may inform best practices by illustrating the relationships between identification hypotheses, methods, and timelines of identification, supporting more efficient resource allocation in long-term unidentified decedent casework.

Abstract Text: In the United States, there are an estimated 40,000 long-term unidentified individuals, constituting a humanitarian concern.[1,2] This issue is further exacerbated by the large number of unidentified migrants from the United States-Mexico border, which is the land-route with the greatest number of deaths worldwide.[3] In fact, United States Border Patrol estimates that over 7,800 people have died crossing the border since 1998, but this number is an underestimation, as many remains are not found.[4] When migrant remains are recovered, there are a variety of Identification (ID) methods that are utilized based on the case circumstances, including DNA comparisons, fingerprint analyses, dental comparisons (primary methods), and the presence of secondary identifiers such as personal effects, tattoos, scars, pathologies, and antemortem trauma.[5,6] Secondary identifiers are often used to provide identification hypotheses, which, depending on the case circumstances, can be accepted as a circumstantial identification or can be confirmed via a primary method of identification. Individuals with secondary identifiers or information for an identification hypothesis may be identified more quickly than individuals with no identifying information, but the relationship between the identification method used and the time to identification for individuals with ID hypotheses has not been explored. This study aims to examine the relationships between how an ID hypothesis is made, the ID method, and the time to identification for migrant cases as well as patterns of migration in identification based on country of origin.

To investigate the relationships between ID method, time, and the mechanisms for ID hypotheses, 30 Operation Identification (OpID) cases were examined. All cases included a presumed identification hypothesis informed by secondary identifiers (e.g., tattoos, personal effects, pathological features), subsequently confirmed using one of three primary methods: DNA, fingerprints, or dental comparison. Data were collected through casefile information and all statistical analyses, including Cramer's V and Fisher's Exact Tests to determine significance between variables, cross tabulations to determine distributions within the sample, and multiple correspondence analyses to examine relationships between multiple variables, were performed using RStudio 4.4.2.[7-11]

Results revealed a significant relationship between ID method and time to identification: individuals identified via DNA or other methods had longer identification times than those identified via fingerprints. Additionally, a significant relationship was found between the type of ID hypothesis and the ID method used, though no significant relationship was found between the hypothesis type and time to identification. Temporal and geographical patterns were noted in two Texas counties, with older cases from Brooks County more often involving individuals from Ecuador, El Salvador, and Mexico. Newer cases, mostly from Maverick County, involved individuals from Guatemala, Honduras, Nicaragua, and Venezuela.

This study highlights the close relationship between identification methods and secondary identifiers and highlights patterns in migration through time. These findings have implications for forensic practice as secondary identifiers can be utilized to form ID hypotheses and are closely related to the identification method used. Future research will expand to include OpID cases lacking initial identification hypotheses and larger sample sizes to assess whether these patterns persist.

A105 Dignity in Death: Developing Remote Case Management and Burial Protocols for Long-Term Unidentified Decedents

Victoria Swenson, PhD, Operation Identification, San Marcos, TX; Molly A. Kaplan, PhD, Operation Identification, San Marcos, TX; Daniela D. Martinez Herrera, BA, Texas State University, Corinth, TX; Abigayle Jose, BA, Operation Identification, San Marcos, TX; Ashley B. Fields, BS, Operation Identification, Erie, PA; Hannah J. Stottlemyre, MA, Texas State University, San Antonio, TX*

Learning Objectives: After attending this presentation, attendees will have a greater understanding of a dignified burial protocol for unknown decedents whose cases will continue to be investigated. This presentation will demonstrate the forensic and archaeological protocols Operation Identification (OpID) implemented for improving case management, traceability, and maintaining dignity of long-term unidentified individuals.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of the high number of deaths causing overcrowding and large-scale burial of unidentified human remains.

Abstract Text: For the past 30 years, migrant fatalities have been steadily increasing and represent a chronic mass disaster that is a product of Prevention through Deterrence policies implemented during the Clinton Administration. Rather than discouraging migration into the United States, these policies have shifted routes to more dangerous terrain. Due to the complexity of death investigation and a fragmented, under-resourced, and overwhelmed medicolegal system in South Texas, many decedents recovered in the region remain unidentified. Additionally, many rural counties along the Texas-Mexico border do not have emergency morgues to store remains for prolonged periods of time. These counties often rely on funeral homes and/or neighboring counties to assist with storage for a daily fee, increasing financial costs (i.e., hundreds of thousands of dollars annually) for the municipality. Due to the extremely high numbers of deaths in these rural communities, funeral homes and mobile morgues are quickly overcrowded, leading to cremations and/or large-scale burial of the unidentified without proper forensic analysis, documentation, or genetic sampling. The Texas Code of Criminal Procedure (TCCP) mandates that unidentified human remains are traced for a minimum of ten years. However, many individuals are often buried without the proper case information and are administratively lost.

In August of 2024, OpID established a remote case management protocol to assist Maverick County with the overwhelming number of unidentified decedents being stored in their emergency morgue. This protocol includes: (1) collecting postmortem fingerprints of decedents in various stages of decomposition; (2) collecting bone samples for DNA analysis; and (3) documenting and photographing the remains and personal effects to be uploaded to the National Missing and Unidentified Persons System (NamUs). Since this implementation, OpID has remotely managed 42 Maverick County cases. To date, 15 individuals have been repatriated, 11 individuals have been identified, and 3 have tentative identifications. However, despite all efforts, 13 cases remain unidentified.

Due to storage constraints, OpID traveled to Maverick County, TX, to assist the Justices of Peace (JPs) with the dignified burial of the 13 unidentified decedents in Quemado Cemetery. Thirteen graves were mechanically excavated to depths of four to four-and-a-half feet. To maintain traceability, OpID recorded each grave using the Trimble R8/R7 Integrated System on the ground surface and base of the grave shaft. The depths of the body at the highest and lowest points were recorded. Stainless steel tags were engraved with case information and were placed on the decedent and body bag before burial. All case documentation was printed, vacuum sealed, and buried with the decedent. Each grave was backfilled and marked with a wooden marker and an additional metal tag. A short letter report and all data, including spatial data, were shared with the county officials to maintain traceability.

The objective of this presentation is to demonstrate that remote case management protocols and traceability methods should become standard practice for jurisdictions without a medical examiner's office. Further, the importance of refining protocols for remote case management to ensure care and dignity of the decedents will be discussed.

A107 Close-Interval Metal Detection of Wreckage at Crash Sites of Large Aircraft to Identify Priority Areas for the Recovery of Human Remains

Lillian S. Antonelli, MA, University of Nevada, Reno, Reno, NV; David A. Bavencoff, Jr., MS, Project Recover, Santee, CA; Andrea Palmiotto, PhD, Indiana University of Pennsylvania, Indiana, PA; Lexi N. Dengah, BA, Brigham Young University, Mukilteo, WA; Francesca M. Fiorello, James Madison University, Ashburn, VA; Axel E. Valdez Ruiz, Franklin and Marshall College, Willow Grove, PA*

Learning Objectives: After attending this presentation, attendees will be aware of the value of close-interval survey and evaluation of material type to supplement site investigations and identify potential excavation locations for the recovery of human remains from crash sites associated with large multi-station aircraft.

Impact Statement: This presentation will impact the forensic science community by evaluating the results of close-interval survey methods to plan recovery efforts at horizontally broad historic aircraft crash sites using a World War II B-17 case study from Germany. While practitioners frequently use metal detection surveys to identify metal-dense areas and recover diagnostic metal pieces associated with missing service members' assigned areas of the aircraft, they do not generally assess the type of non-diagnostic materials. Evaluating the different types of non-diagnostic metal, especially when used in conjunction with other survey methods, may assist in strategizing recovery efforts at large and complex recovery sites.

Abstract Text: Creative problem solving is required to approach complicated, historic, conflict-related aircraft crash sites toward the recovery of probative remains Wreckage is often propelled with massive force from an aircraft crash site following the trajectory and momentum of the crash, but aircraft with ordnance may explode upon impact and expel shrapnel from the blast seat with more fragmentation, varying arcs, and different trajectories than aircraft without ordnance.

Most commonly, archaeologists use metal detection at crash sites to identify areas with high metal counts and diagnostic materials (e.g., steering column for pilots, rank insignia, and personnel identification tags) and situate units for excavation.[1,2] If diagnostic wreckage is not identified or is not directly associated with possible human remains, practitioners need other means to strategize recovery efforts at crash sites involving the loss of large multi-station aircraft. However, most practitioners do not evaluate material type in any meaningful manner to forward investigations.

Aluminum, cast iron, and stainless steel were common components of WWII aircraft.[3,4] Lightweight aluminum was the main component of the aircraft skin. Heavy cast iron contributed to bomb casings. However, human soft tissue and bone are lighter than these metals. Other variables notwithstanding, the heavier materials should be ejected farther than human remains at the same trajectory and force.[5] Therefore, areas with higher quantities of iron and steel relative to aluminum may represent unlikely areas for recovery of human remains, but areas with lower frequencies of heavier metals may represent more appropriate potential recovery areas for human remains.

This B-17 case study explores a widespread, shallow aircraft crash site with a roughly west-to-east trajectory. This area was initially delineated as a 110-m^2 area through wide-interval (20-m transect) metal detection survey. Select areas of the site were subjected to close-interval metal detection and pedestrian survey to better understand site boundaries and distribution of materials toward the recovery of human remains. Spatial positioning and material type were recorded for each metal object recovered from incident-related strata. Excavation units were situated based on observations from these surveys. Potentially probative materials were subsequently recovered within and outside the initial site boundaries.

Results confirm that aluminum is ubiquitous across the site and typically comprises 65–95% of metal in designated areas. Iron and steel generally increase in relative frequency as recovery efforts moved east beyond the impact crater, ranging from 1–20% per area. This patterning was largely consistent between survey and excavation efforts. Moreover, most potential evidence was recovered in areas with lower quantities of iron and steel. This suggests that assessment of material type may offer a quick, effective means of identifying potential excavation areas in large and complex sites. When incident markers have been obscured on the landscape, close-interval survey methods may narrow down potential areas for excavation. When investigating historic aircraft crash sites where bombs detonated during the impact process, we recommend that practitioners expand their focus beyond emphasis on diagnostic pieces of wreckage related to aircraft stations and consider specific wreckage material types.

A108 An Evaluation of the Use of Alternate Light Sources in the Search for Burned Skeletal Remains

Jessica Lucia, MA, Virginia Commonwealth University, Richmond, VA; James A. Russell, BFA, Search and Rescue Tracking Institute, Virginia Department of Emergency Management, Virginia Beach, VA; Tal Simmons, PhD, Virginia Commonwealth University, Jerusalem, Yerushalayim, Israel; Stephen Stockman, MPA, Virginia Commonwealth University, Richmond, VA; Jenise Swall, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: This presentation will provide information regarding the efficacy of using several Alternate Light Sources (ALS) in locating burned and unburned skeletal remains in wooded environments. After attending this presentation, attendees will better understand the ways in which thermal damage changes the fluorescence of bone and how the use of ALS in searches for skeletal remains is affected when remains have been exposed to fire.

Impact Statement: Comparison of searches with ALS for burned and unburned bones showed significant differences in recovery rates. These results may prove beneficial to personnel involved in searches for human skeletal remains by guiding decision-making regarding the use of daylight searches versus nighttime searches with ALS in order to maximize the recovery of whole and/or fragmentary skeletal elements.

Abstract Text: In searches for skeletal human remains, the ability to recover as complete an individual as possible is of utmost importance for purposes of identification and trauma analysis. ALS have become increasingly common as a tool in searches for skeletal remains, due to the fluorescent properties of type 1 collagen and hydroxyapatite found in bone. While the effectiveness of using ALS at night in search scenarios versus daylight searches has been demonstrated, ALS effectiveness in searches including thermally damaged bones has not yet been explored.[1] Given both the increase in wildfires throughout North America and other parts of the world in recent years, and the fatalities resulting from these fires, enhancing recovery rates of skeletal remains is paramount.

Mammalian livestock bones were burned in wood fires to varying degrees; temperatures of the fire were recorded using a Seek Thermal FirePRO 300 thermal camera every ten minutes. The temperatures of each area of the fire were noted and correlated to the appearance of the bones in those areas. Twenty-seven daytime and nighttime searches were performed by individual volunteers who belong to Search And Rescue (SAR) organizations throughout the Commonwealth of Virginia and certified by the Virginia Department of Emergency Management.

Each volunteer had been fully trained in skeletal search techniques and all had search and recovery case experience. Both burned bones and unburned controls were scattered and partially concealed under leaf litter and brush in 2,500 ft 2 zones of eastern deciduous forest. Volunteers searched for up to one hour, using a line search pattern. Nighttime searches, also limited to one hour, were conducted using handheld uvBeast or Crime-lite ALS devices paired with filtered safety glasses; these devices produced ultraviolet (385-395 nm), violet (395-425 nm), or blue (420-470 nm) light, each of which was tested in searches three times each.

Preliminary results indicate that: (1) overall recovery rates for burned bone were lower than those for unburned bone, (2) the impact on recovery rate varied by level of burn damage, and (3) violet light was associated with the highest recovery rates, although all three wavelengths tested can be considered adequate for use in searches for human remains in which thermally damaged bones are expected or known to be present.

A109 Ground Penetrating Radars in Forensic Anthropology: Evaluating Efficacy Through Controlled Systematic Surveys

Dawson W. Lamb, MA, Louisiana State University/FACES Lab, Baton Rouge, LA; Anthony V. Lanfranchi, MS*, Louisiana State University/FACES Lab, Baton Rouge, LA*

Learning Objectives: Attendees will learn how Ground Penetrating Radar (GPR) can be systematically applied to locate human remains in subsurface graves in the absence of burial containers such as coffins. The presentation will provide a detailed description of the ability of GPR in detecting human remains by demonstrating specific data acquisition protocols, post-processing techniques, and interpretation of radar anomalies in forensic settings.

Impact Statement: This study enhances practitioner competence by demonstrating validated GPR protocols using known-location human burials under realistic field conditions. These findings can directly impact stakeholder outcomes by aiding faster, more accurate location of buried remains in both forensic and humanitarian investigations.

Abstract Text: This study seeks to answer the question: How can ground-penetrating radar be optimized to more accurately identify buried human remains? Forensic anthropologists are often tasked with locating and identifying human remains that may be buried in clandestine or unmarked graves. While GPR has become an increasingly common tool in forensic applications, much of the published research relies on case studies or non-human proxies, limiting its real-world applicability.[1-3] This study addresses that gap through the systematic survey of four marked burials of willed human remains interred at the Louisiana State University Forensic Taphonomy Education and Research Facility (FTERF). The variables of each burial, including location, postmortem interval, and burial dimensions, are well documented, allowing for a controlled, realistic assessment of GPR performance.

A 4m x 17m survey grid was established to encompass the four burials, with 0.5m transects to ensure adequate coverage. A Noggin 500 MHz GPR system with a SmartCart was used to collect data, targeting a depth of 2 meters, consistent with settings from previous research. Data were processed and analyzed using multiple platforms, including EKKO Project and Surfer. GPR anomalies associated with the burials were most distinct in the 0.3–0.4m depth slice, which corresponded closely with the known vertical position of the remains, despite the absence of burial containers. Anomalies identified in the EKKO software aligned with burial locations and depths between 25–30 inches (0.64-0.76m). In Surfer, gridded data visualizations reinforced the spatial correspondence of anomalies with the interments.

This study provides support for the use of GPR in detecting human remains in forensic conditions. By evaluating GPR's impact on known-location human burials, it offers a rare empirical dataset that bridges the gap between experimental and applied GPR use. The findings support GPR as a reliable tool for forensic anthropologists and law enforcement personnel tasked with locating buried remains. Additionally, the comparative analysis of software platforms informs practitioners about differences in visualization outputs and interpretive utility.

The role of ground-penetrating radar in detecting buried human remains can be vital to forensic anthropologists and law enforcement personnel by reducing the time and resources needed to locate subsurface graves. The current study surveys four marked burials each containing donated human remains at the LSU FTERF. This research builds on prior studies by validating the effectiveness of GPR in detecting buried human remains and highlighting best practices and methods for its optimal use in forensic contexts. A more comprehensive understanding of GPR optimization can provide crucial information on how to detect human remains in both marked and unmarked burial sites, as well as other forensic settings.

A110 Anthropological Approaches to Identification in a Historic World Ware II Aircraft Loss: The Crew of *Little Joe*

Catherine R. Jones, PhD, SNA International, LLC, Omaha, NE; Katie East, PhD, SNA International, LLC, Omaha, NE; Carrie A. Brown, PhD, Defense POW/MIA Accounting Agency, Omaha, NE*

Learning Objectives: Attendees will learn about the challenges of resolving commingling in complex historic aircraft losses and the most effective strategies for resolving commingling and identifying multiple individuals from such losses using standard anthropological protocols.

Impact Statement: The keys to successful identification of the *Little Joe* losses included collaboration, open and communicative peer review, effective data management, detailed record keeping, and a wide knowledge of anthropological and identification methods. These lessons can be applied to diverse types of case work in both historic and modern forensic contexts.

Abstract Text: Resolution of commingling from multi-individual aircraft losses presents numerous challenges, including fragmentation, taphonomy, diverse and overlapping trauma signatures, and large quantities of evidence. Compressed timelines and multiple stakeholders increase the complexity of analysis in historic aircraft losses. We present the anthropological analyses for the case of the WWII aircraft *Little Joe*, which involved the April 8,1944, loss of ten crew members of a B-24 aircraft. The resolution of this case involved multiple lines of anthropological analysis resulting in the resolution of all ten individuals.

Anthropological methods were employed throughout the analysis and included visual pair matching, assessment of articulation, fracture/fragment refitting, taphonomic observations, trauma interpretations, and estimation of the biological profile. Additionally, integrating archaeological data obtained from the field during on-going excavation enabled the anthropologists to work through associating remains to individuals in real time. Importantly, the anthropological analytical process was iterative. Standard protocols were followed, each time incorporating additional information. For example, all remains were initially inventoried and the minimum number of individuals was estimated, which informed the DNA sampling strategy. Once DNA was submitted, the anthropologist continued to work on sorting the remains and estimating components of the biological profile. As DNA results were returned, the anthropologist incorporated those results into further sorting and association of remains, including illuminating consultation with forensic odontologists.

The integration of multiple lines of anthropological analysis, close and open collaboration, team flexibility, and meticulous record keeping allowed for the identification of all ten individuals in this case. In total, 1,255 evidence exhibits representing a minimum of 1,758 fragments were analyzed, 72 skeletal and dental samples were submitted for DNA analysis, and 252 osseous exhibits were successfully segregated into ten individuals. The success of the anthropological methods used resulted in an inclusion of 3.5 times more elements per person than DNA alone. The remainder of fragments were resolved through a group report, which required meticulous accounting of and peer review of over 1,000 remaining fragments. Advanced inventory systems, data visualization platforms, and transparent and detailed record keeping were employed to allow simultaneous investigation by multiple subject matter experts and ongoing, flexible analysis in light of multiple rounds of evidence recovery and DNA analysis.

A111 From Chaos to Connection: Reassociating Arm Bones in Commingled Contexts

Anna S. H La Valley, MSc, University of West London, Reading, England, United Kingdom; Erica Baer, PhD, Kean University, Union, NJ; Xenia Paula Kyriakou, PhD, University of Montana, Fort Myers, FL*

Learning Objectives: This presentation will support the use of predictive modeling methods for reassociation of commingled remains. After viewing this presentation, attendees will better understand the prospects of employing statistical analysis for sorting commingled remains.

Impact Statement: Traditional methods of estimating the number of individuals within commingled remains are reliant on pairwise predictions of Minimum Number of Individuals (MNI) or Minimum Number of Likely Individuals (MNLI) matching. The introduction of reassociation at an earlier point in the process provides more precise MNLI estimates.

Abstract Text: With an individual consisting of 206 bones, commingled remains sorting resolutions become exponentially difficult depending on the number of individuals and the conditions of the remains when recovered.[1]Pair matching and inventory count provide the standard MNI, calculated through simple regression equations but is most precise within known, or "closed," case populations, such as a plane crash.[2] The Lincoln-Petersen index (LPI) is a statistically accurate expansion on the MNI method that provides the MLNI within unknown, or "open," population commingled context, such as a mass disaster.[2-4] Both MNI and LPI accuracy was developed using paired elements and is affected by completeness and homogeneity of the remains. Exploring the validity of osteometry association predictions could increase the accuracy of both MNI and MLNI estimates.

This study compares the predictability of reassociating upper limb bones using only the maximum length measurement on each bone. The study included humerus, radius, and ulnar max length measurements from 190 individuals (167 left sets, 158 right sets, and 134 combined left/right sets) from the Cyprus Research Reference Collection, a 19th/20th-century documented skeletal collection in Cyprus with known age and sex. These measurements were used to evaluate blind reassociations of the upper limb long bones by side.

Two regression models were developed to sort commingled bones of the articulating upper long bones: simple, one element to one element, and multiple, two elements to one element. Additional testing of both simple and multiple models was conducted with sex as a predictor. The simple regression equations developed presented strong positive linear relationships in the Pearson's Correlation coefficient ($R = 0.73\text{-}0.96$, $p < 0.001$). The values of the determined coefficient statistics were found to be high ($R2 = 0.76\text{-}0.93$), and the Root Mean Standard Error (RMSE) remained low (RMSE = 4.78-10.13). When sex as a predictor was considered, coefficient statistics degraded ($R2 = 0.55\text{-}0.93$), and the Standard Error increased (RMSE = 3.14-10.7). In the multiple regression analysis, the linear relationships and errors showed similar results, with one marked difference. The left forearm demonstrated that males were significant predictors in both simple and multiple models. All analyses were evaluated using JMP Student Edition 18.2.1.

The results indicate that linear regression models provide highly accurate predictions, with the multiple regression models outperforming the simple regression models. The MNI of this population is estimated at 167 individuals, and the MNLI was calculated to be at 196 individuals. The MNI underestimates the population by 12% and the MNLI overestimates the sets but stays within the observed number of individuals. Reassociation demonstrated a 15% improvement in the MNI of right sided sets and 19% improvement in left sided sets. The estimated MNI would improve overall by 3%. This would halve the distance between the MNI and MNLI estimates. This study revealed improvement on the effects of homogeneity on MNI; further study is required to determine how the effects of fragmentary remains and pathology within this population affect this result.

A112 Occipito–Atlas Reassociation in Commingled Skeletal Remains

Anna S. H La Valley, MSc, University of West London, Reading, England, United Kingdom; Stavri Karasiali, MSc*, University of Amsterdam, Limassol, Northern Cyprus, Cyprus; Erica Baer, PhD, Kean University, Union, NJ; Xenia Paula Kyriakou, PhD, University of Montana, Fort Myers, FL*

Learning Objectives: Attendees will learn how to apply predictive modeling to reassociate crania with C1 vertebrae in commingled skeletal remains using morphometric measurements. They will understand how to interpret regression outputs, assess the impact of sex as a covariate, and evaluate the limitations and potential of statistical tools in forensic reassociation protocols.

Impact Statement: This study presents a novel, population-specific approach for reassociating crania and C1 vertebrae in commingled skeletal contexts using morphometric analysis. Although the method's predictive power is limited, it offers a statistically grounded tool to support more accurate sorting and reassociation, particularly in forensic investigations involving fragmented remains. It contributes to the development of regionally relevant protocols for identification in post-conflict or mass fatality settings.

Abstract Text: Craniovertebral reassociation remains a persistent challenge in the analysis of commingled skeletal remains, especially in forensic and post-conflict investigations. Previous research has highlighted the anatomical and biomechanical connection between the cranium and upper cervical spine, proposing this region as a viable target for reassociation.[1-4] The craniovertebral junction, while not perfectly predictive, appears morphometrically consistent enough to serve as a supplementary tool in commingled remains analysis, particularly when used in conjunction with sex estimation.

Sex estimation is a cornerstone of the biological profile and plays a critical role in narrowing identification possibilities and guiding the interpretation of age, ancestry, and stature.[5] However, its accuracy depends on population-specific standards, as skeletal morphology is influenced by genetic, environmental, and ecological factors.[6-8] Numerous studies have shown that applying osteometric models outside their original populations significantly reduces their reliability, reinforcing the need for regionally derived forensic reference data.[9-12]

The Greek-Cypriot population, shaped by Mediterranean, Middle Eastern, and European ancestry, remains underrepresented in forensic standards. Given Cyprus's history of conflict and unresolved disappearances, this population presents both a need and an opportunity for regionally tailored forensic tools.

This study investigates whether morphometric relationships between the occipital condyles and the first cervical vertebra (C1) can support accurate reassociation of skulls to vertebral columns. Specifically, it evaluates whether the maximum anteroposterior length of the articular surfaces offers predictive value in identifying matching cranium–atlas pairs.

A total of 120 adult individuals (70 males, 50 females) from the Cyprus Research Reference Collection (CRRC; 1975–2015) were selected. Bilateral maximum condylar lengths of the occipital bone and the superior articular facets of C1 were measured using a digital caliper (to 0.01 mm precision). Two regression models were developed to assess whether occipital condyle dimensions could predict corresponding C1 measurements, with sex included as a covariate. All statistical analyses were performed using JMP Student Edition 18.2.1.

The resulting equations showed moderate positive linear correlations between the occipital and atlas condylar lengths ($R = 0.45–0.47$). However, the coefficient of determination remained low ($R^2 = 0.20–0.22$), suggesting that only ~20% of the variation in C1 measurements could be explained by occipital dimensions. Sex-specific models improved prediction slightly, especially in females ($R^2 = 0.30$; RMSE = 1.93). Despite the limited predictive power, the low root mean square error (RMSE = 2.11–2.19) indicates a relatively narrow range of variation that may help eliminate mismatches during sorting.

This study provides an early framework for morphometric reassociation based on region-specific data and contributes to the growing body of evidence supporting the use of head and neck anatomy in forensic identification.

A113 Examining Contributing Factors to Natural Human Mummification at FOREST in Cullowhee, North Carolina: A Continued Investigation

Alex D. Vacca, University of Nebraska-Lincoln, Hillsborough, NC; Kaleigh C. Best, PhD, Western Carolina University, Cullowhee, NC; Rebecca L. George, PhD, Western Carolina University, Cullowhee, NC*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the effect of seasonality on the rate of mummification in relation to aggregate, humidity, temperature, and precipitation. Mummification patterns at Western Carolina University's Forensic Osteology Research Station (FOREST) will be discussed.

Impact Statement: This study expands knowledge in the field of human taphonomy by investigating how seasonal variation, temperature, humidity, and precipitation influence rates of mummification, a currently understudied topic, specifically as it relates to its occurrence in temperate climates, as well as potential implications for the impact of mummification on the ability to determine the Postmortem Interval (PMI).

Abstract Text: Natural mummification occurs across various global environments, including in temperate climates, yet the mechanisms behind it remain poorly documented.[1] Improving the understanding of mummification patterns in these climates can assist forensic specialists in refining estimations of the PMI. A 2024 literature review demonstrated that data in current literature are inconsistent and lack specificity concerning temperate zones, indicating a pressing need for targeted research.[1]

This study expands knowledge in the field of human taphonomy by investigating how seasonal variation, temperature, humidity, and precipitation influence rates of mummification. Previously presented initial research conducted at Western Carolina University's FOREST examined 12 donors over a 16-month period.[2] Donors were placed supine and left uncovered on the ground surface. The Total Body Desiccation Score (TBDS), developed by Connor et al. was used to score the donors daily, from deposition until recovery.[3]

Environmental data on temperature, humidity, and precipitation were collected via the National Weather Service's historical records from the Jackson County Airport. To examine possible patterns of mummification, data were organized to compare contributions to initial and total mummification. Statistical results from the pilot study, conducted in 2024, indicated that only temperature and humidity significantly influenced the timing of initial mummification, while temperature, humidity, and precipitation all contributed to total body desiccation. Seasonal effects were notable, with fall showing particular significance in the rate of mummification.

To strengthen findings, the study was expanded to 30 donors following the same protocol as the previous study.[2] Prior to statistical analysis using RStudio, two donors were excluded as these donors underwent autopsy prior to placement.[4] Data were assessed for normality using Q-Q plots and Shapiro-Wilks tests. Statistical relevance of contributing variables were analyzed using Multivariate Analysis of Variance (MANOVA) and Tukey's post-hoc comparisons. Cohen's Kappa was applied to gauge intra-observer reliability, revealing a fair level of agreement ($\kappa = 0.28$) between two scoring rounds which took place approximately 3-6 months apart.[5]

Results indicate that all three environmental variables (temperature, humidity, and precipitation) correlate significantly with both the onset and completion of mummification. For total mummification, interactions between temperature and precipitation, humidity and precipitation, and temperature and humidity proved statistically significant. Additionally, it was revealed that for both first and total mummification, seasonality is significant. However, only the interaction between summer and fall can be isolated as significant to the timing of total mummification. Other interactions between spring and fall, and summer and fall relating to the onset of mummification are approaching significance, suggesting that environmental variables during these times are especially important in the occurrence of mummification.

This research validates the relationship between environmental factors and natural mummification in temperate zones, particularly in Western North Carolina. Findings contribute valuable insight into forensic anthropology and underscore the importance of seasonality when interpreting decomposition timelines specifically in cases of natural mummification. The study also lays groundwork for exploring untested variables, particularly positionality, that may influence mummification. It emphasizes the importance of factoring in mummification when estimating PMI to improve accuracy across diverse climates.

A114 Terrestrial Scavenger Activity on Human Remains at FROST

Emma Gariepy, BSc, Mayo Clinic, Schoolcraft, MI; Hayden S. McKee-Zech, PhD, Northern Michigan University, Marquette, MI*

Learning Objectives: After this presentation, attendees will understand the documented terrestrial scavenger guild at the Forensic Research Outdoor Station (FROST) as well as the characteristic scavenger activity on human remains at the FROST facility.

Impact Statement: This presentation will benefit the forensic science community by informing first responders of common scavengers in the northern Michigan area. The results provide a reference point for striped skunk and red fox patterns of scavenging on human remains in the unique environment of FROST and the Upper Peninsula of Michigan.

Abstract Text: Scavengers, like the striped skunk (*Mephitis mephitis*) and red fox (*Vulpes vulpes)* actively contribute to decomposition; however, not much is known about their activity types, population dynamics, or patterns of scavenging.[1,2] This research was conducted at the Northern Michigan University human decomposition facility, FROST, in Marquette, MI, from fall 2018 to spring 2025. The FROST facility consists of a fenced one-acre grassy field, no tree cover on the shores of Lake Superior in an urban environment. FROST experiences long cold winters, average temperature -7.6°C with an average yearly snowfall of 188.5 inches, and humid summers with an average temperature of 17.8°C.[3] A total of 18 human donors were placed unclothed supine on the soil surface under scavengers exclusion cages and monitored for scavenging. No enrollment restrictions (weight, age, trauma) were placed on these donors. This project hypothesized that scavenger guilds, activity, and patterns of consumption are distinctly different from facilities with warmer and/or drier climates in the United States and globally.[4-8] Trail camera footage was analyzed to examine the terrestrial scavenger activity, population diversity, and abundance over decomposition. This data was categorized by activity type, body region, number of animals, time of activity, and the season.

The results of this study indicated that the scavenger guild inside the FROST facility consisted of striped skunk (1976), red fox (528), groundhog (4), rabbit (289), cat (135), and mouse (1) from a total of 2,935 of observations. We found that the activities and pattern of scavenging by the scavenger guild varied by individual donor; however, only 5 out of the 18 donors had documented scavenging on the trail cameras. Summer was the most active season, with animals documented in 1,305 instances. Both spring and fall had 907 and 716 documented instances, but winter was the least active season by far with only 7 instances of documented scavenging activity. In general, the striped skunk preferentially scavenged the limbs (45%) and head (34%) of human remains. Alternatively, the red fox was seen primarily scavenging the groin area (75%). The groundhog, rabbit, cat, and mouse were not seen consuming the human remains. Most of their activity was spent passing by, but the groundhog was interested in the human remains a quarter of the time (25%), whereas the rabbit and cat were only interested 1% and 13% of the recorded instances, respectively. The mouse was only documented on the trail camera once, running on the scavenger exclusion cage with no interaction with the remains. The striped skunk (67%) and red fox (18%) were the primary recorded species of terrestrial scavengers, and this is consistent with results from Smith and Wankmiller.[2]

A115 The Importance of Scene Context in Anthropological Time-Since-Death Estimation: "Back to the Basics" of PMI

Ariana N. Strasheim, MA, Sheridan County Coroner's Office, Sheridan, WY; Allysha P. Winburn, PhD*, University of West Florida, Pensacola, FL; Taylor Walkup, MA*, University of Tennessee, Knoxville, Knoxville, TN; Emily Romdemne, MA*, University of Wisconsin-Platteville, Madison, WI*

Learning Objectives: After attending this presentation, attendees will learn how an anthropological approach to estimating Postmortem Interval (PMI) can be enhanced by the archaeological concept of *terminus post quem*: contextual data from the death scene can inform an understanding of the earliest date on which the death could have occurred.

Impact Statement: This presentation will impact the forensic science community by affirming the importance of a holistic and collaborative anthropological approach to the estimation of PMI. These preliminary findings suggest that the most accurate time-since-death estimates are generated when forensic scientists consider not only complex and difficult-to-model decompositional data but also straightforward, observational data from the death scene. Following an anthropologist's blind analysis of the remains, collaborating with death investigators to sequentially unmask contextual data from the scene could improve the precision and accuracy of their PMI estimates.

Abstract Text: Forensic anthropologists are often tasked with estimating the PMI. Traditional anthropological approaches to PMI are decompositional, incorporating observations of the body with temperature data to calculate a quantitative time-since-death interval.[1-3] However, an equally anthropological approach to estimating PMI would rely on scene context, using the archaeological concept of *terminus post quem* to inform a determination of the earliest date on which the death could have occurred.

This preliminary study compared the two approaches—"decompositional" and "contextual"—using a small sample of anonymized cases. Due to the sheer quantity of variables that can impact the accuracy of decomposition-based estimates, it was predicted that "contextual PMI" would be more informative than "decompositional PMI."

From all death investigations conducted between 2023-2025 in Sheridan County, WY, cases exhibiting evidence of decomposition were selected (n=11). Following the methods outlined in Megyesi et al. and applying the corrected equation in Smith et al. and Moffatt, the Total Body Score was assessed for each decedent from scene and exam photographs and paired with temperature data to calculate the "decompositional PMI."[1-3] To inform the "contextual PMI," material evidence from death scenes was reviewed, including phones, calendars, receipts, and pill containers. For example, if a decedent stopped opening text messages and writing in their daily calendar nine days ago, their "contextual PMI" would be nine days. These estimates were compared with the official date of death, which considered not only these factors but also data from interviews with kin and acquaintances.

"Decompositional" point estimates ranged from 3.2 to 19.7 days; 95% Confidence Intervals (Cis) ranged from 1.3-7.9 days to 7.7-49.8 days and were accurate in 9/11 (82%) of cases. "Contextual," *terminus post quem* estimates ranged from ≤2 days to ≤63 days and were accurate in 100% of cases. The estimates were generally similar, indicating a correspondence between the approaches and suggesting that multiple lines of evidence can reinforce an estimate of PMI. However, "contextual PMI" was closer to the actual death dates than "decompositional PMI" in 6/11 (55%) of cases, and in two instances, the 95% "decompositional" CIs were considerably more recent than the "contextual" ranges (e.g., one "decompositional" range was 4.6-29.4 days, but the death occurred 63 days prior and was precisely estimated by the "contextual" range). While technically, these CIs were accurate, the "decompositional" data, if taken in isolation, would have excluded from consideration persons missing for 30+ days, potentially stymying identification efforts.

These preliminary results remain to be replicated on a larger sample. Still, they suggest that PMI estimates need not necessarily rely on difficult-to-model decomposition data to achieve accuracy. Practitioners should consider a shift "back to basics" to focus not only on complex decompositional data but also on straightforward, contextual material evidence easily and quickly collected from the scene. Ultimately, the most anthropological approach to estimating PMI is a holistic and collaborative one—considering first decompositional and then contextual factors to improve the power of PMI to advance death investigations and promote case resolutions.

A116 The Effects of Obesity on Decomposition by Measuring Mass Loss Percentage and Postmortem Interval Estimation

Paige N. Jackson, MA, Texas State University, San Marcos, TX; Danny J. Wescott, PhD, Texas State University, San Marcos, TX*

Learning Objectives: The attendee will identify how obesity, measured by Body Mass Index (BMI) and body fat percentage, may influence human decomposition and Postmortem Interval (PMI) estimations. They will also understand the relationship between Total Body Score (TBS), Accumulated Degree Days (ADD), and body mass loss during decomposition. Lastly, the attendee will evaluate the limitations of current forensic literature in accounting for body mass variation and challenge assumptions regarding decomposition rates in individuals with varying body masses.

Impact Statement: This presentation enhances practitioner competence by providing new data on the relationship between obesity and decomposition, challenging previous notions and assumptions about body composition and decomposition rates. By refining PMI estimation methods through the use of mass loss and TBS, the findings can improve forensic anthropologists' abilities in real-world casework. Ultimately, this research contributes to more accurate analyses in medicolegal investigations involving individuals across a range of body compositions.

Abstract Text: The relationship between obesity and human decomposition is not widely studied. Previous studies have lacked an understanding of the effect obesity has on human decomposition or how the percentage of body mass in similar-sized individuals affects decomposition rates. This study examines the effect of obesity, represented by BMI and Body Fat percentage (BF%), on decomposition by measuring mass loss percentage to provide more accurate estimations of the PMI.

BMI was calculated by dividing the individual's weight in pounds (lbs.) by the square of their height in inches (in.). The BF% was calculated using a series of ultrasound measurements performed with the BodyMetrix BX2000 personal ultrasound and the associated BodyView software.[1] The donors were assigned to their respective BMI and BF% groups (underweight, non-obese, overweight, obese, and morbidly obese). The TBS method was utilized to estimate the PMI in ADD to explore the relationship between TBS and body mass loss.[2]

Sixteen donors from the Whole-Body Donation Program (WBDP) at the Forensic Anthropology Center at Texas State (FACTS) were weighed throughout the decomposition process. The donors were placed supine on the ground surface on metal fence panels with four carabiners attached to the panels. The weight was then measured using four chains suspended from a metal A-frame with a manual chain pulley system and a crane scale affixed to the top. This method was chosen as it did not significantly impact the donors or their decomposition progression. The results indicate no significant relationships between TBS and mass loss during decomposition or between the overall weight, percent body mass loss, and ADD. Furthermore, there are no significant differences between BMI and BF% groups and their effect on body mass percentage loss during the decomposition stages.

Additional research is needed to further understand the correlation between mass loss and TBS when detecting decomposition changes in human cadavers during advanced decomposition stages. Future research can not only refine the understanding of the impact of these factors on decomposition processes and improve forensic methods but also challenge common misconceptions in forensic anthropology, such as the belief that larger individuals decompose at a faster rate.

A117 A Preliminary Study of Human Decomposition in Aquatic Environments in Greece

Christina Karydi, PhD, National and Kapodistrian University of Athens, Alimos, Attiki, Greece; Giorgos Kyros, MSc, National Observatory of Athens / Meteo.gr, Kozani, Kozani, Greece; Konstantinos Moraitis, PhD*, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Kostas Lagouvardos, PhD, National Observatory of Athens, Athens, Attiki, Greece*

Learning Objectives: Attendees of this presentation will gain information on the decomposition patterns of human remains recovered from various aquatic environments in Greece as well as the impact of environmental and contextual factors on decomposition rates. The study evaluates the applicability of existing decomposition scoring protocols and examines the use of Accumulated Degree Days (ADD) in estimating the Postmortem Submersion Interval (PMSI). Although no reliable PMSI estimation equations could be developed, the study addresses significant methodological limitations and includes a broader range of case types, such as partially submerged or washed-ashore remains, highlighting the variability that future forensic models must account for.

Impact Statement: This presentation contributes to the forensic science community by expanding the practitioners' understanding of decomposition variability across different aquatic environments, including complex scenarios. These findings support more informed and accurate application of Postmortem Interval (PMI) estimation protocols in real-world forensic investigations.

Abstract Text: Accurate estimation of the PMI is essential in forensic investigations. Aquatic decomposition studies remain underrepresented, especially in the Mediterranean region.[1] Bodies in aquatic settings decompose at a slower rate and are exposed to constantly changing biological and physicochemical conditions due to their continuous vertical and horizontal movement.[2,3] Decomposition patterns may also vary between anatomical regions of a floating body, depending on whether they are submerged or exposed.[3] Similar differences are observed in bodies found in tidal zones or bathtubs, due to periodic or partial immersion.[4,5] Such variability is often present in real forensic cases and complicates the interpretation of decomposition patterns.

This study focused on the examination of the postmortem changes of 41 bodies recovered from various aquatic environments in Greece (mostly marine) between 1999 and 2022. The goal was to evaluate decomposition in relation to time-since-death indicators, including ADD and PMSI, and assess whether reliable estimation equations can be developed. Decomposition was evaluated using the Heaton et al. protocol, but also hybrid scoring methods combining terrestrial (Megyesi et al. protocol) and aquatic systems.[2,6] Soft tissue breakdown, mummification and adipocere formation, disarticulation patterns, and skeletal exposure were examined, and the rate of decomposition was evaluated in relation to the environmental parameters, such as water salinity, flow velocity, temperature, and seasonal variation.

Results showed that soft tissue decomposition and skeletal exposure occurred faster in marine environments than reported in existing literature. Saponification was observed in 42.1% of cases, sometimes within days, likely due to the warmer Mediterranean water conditions that accelerate bacterial activity. Mummification was rare (21%) and limited to bodies that had floated or washed ashore and were exposed to sunlight. Disarticulation followed expected patterns, with the head, mandible, and extremities disarticulating earlier. Statistical analysis revealed only moderate correlations between Heaton's decomposition scores and PMSI ($R^2 = 0.387$), even after excluding non-marine cases ($R^2 = 0.393$). This suggests that the variability of the data is primarily due to the fluctuating conditions in marine environments than the heterogeneity of the sample. The combined use of aquatic and terrestrial protocols in cases of bodies that were floating, found partially into water, or were washed ashore did not improve the results. However, stronger correlations were found between decomposition scores and ADD ($R^2 = 0.499$), suggesting that temperature is a significant factor in estimating PMSI, similarly to terrestrial models. Nonetheless, based on this sample, the correlations were not strong enough to develop robust PMI estimation equations. Salinity and water flow significantly influenced the rate of decomposition, which was greater in saltwater and high-flow environments. Seasonal variation was also significant, with decomposition proceeding more quickly during summer and autumn.

This study constitutes the first detailed analysis of aquatic decomposition in Greece and highlights the limitations of existing protocols in estimating the PMSI. The findings highlight the need to develop regionally adapted models for the unique characteristics of Mediterranean aquatic ecosystems to improve PMI estimation in forensic investigations.

A118 A Test of Thermal Damage Recording Systems With Advancing Decomposition

Mariah E. Moe, PhD, Texas State University, San Marcos, TX; Sophia R. Mavroudas, PhD, Forensic Anthropology Center at Texas State, San Marcos, TX; Danny J. Wescott, PhD, Texas State University, San Marcos, TX; Hailey Collord-Stalder, MA, Oregon State Police, Clackamas, OR*

Learning Objectives: After attending this presentation, attendees will better understand the effect that advanced decomposition has on a practitioner's ability to utilize thermal damage recording systems for fire death investigation.

Impact Statement: This presentation will impact the forensic science community by highlighting the need to critically evaluate the potential that pre-burn decomposition stage affects the applicability of thermal damage recording systems in fatal fire scenes and to consider decomposition state when interpreting these scenes.

Abstract Text: The methods involved in forensic fire death investigation are complex, requiring multi-disciplinary coordination among fire departments, law enforcement, and forensic specialists. In fatal fire scenes, the human remains themselves can provide critical interpretative information for understanding the origin, duration, and intensity of the fire. Forensic anthropologists have long been involved in the recovery of human remains after fire events and have recognized consistent patterns in how the human body changes under extreme heat conditions. Standardized systems to document these changes were developed during real-world events and refined in experimental studies using willed body donors. These systems all assume that the individual was fully fleshed and in a fresh state prior to exposure to extreme heat or fire. It was thus the purpose of this study to determine whether advanced stages of human decomposition affect the overall pattern of thermal damage exhibited on remains in fire scenes and to evaluate whether the frequently used thermal damage recording systems are appropriate for documenting the thermal changes to remains in various stages of decomposition.[1-3]

In this study, N=14 donors were utilized at varying stages of decomposition in experimental fire scenarios. Immediately prior to burning, each donor was assessed for total body score and assigned a decomposition stage of fresh, early, advanced, or skeletal.[4]

Two donors who were assigned to different stages of decomposition were placed in pairs across seven fire scenarios, including structure and vehicle fires. Controlled fires were set for each scenario with the fire ignition source, fuel, and suppression efforts held constant between the scenario types. All fires were extinguished according to approximate national fire department response times for intervention. After burning, all donors were assessed for thermal changes according to procedures outlined in the recording systems noted above. Each donor was evaluated by two independent scorers.

The results of this evaluation indicate that a general increase in the degree of thermal alteration was seen with advancing decomposition in the Pope et al. and Williams systems, but not in the Glassman and Crow system.[1-3] Overall, different stages of decomposition prior to burning resulted in donors with different levels of burning in the same paired fire scenario with the exception of one case in which no significant differences were noted between the donors.

This research shows the need to consider decomposition as a factor that could lead to varying levels of burning in fire deaths with more than one decedent. This research also demonstrates the restrictions inherent to the current systems of thermal damage recording and provides recommendations for adjusting the descriptions of thermal alteration in human remains.

A119 The Accuracy of PMI Predictions in GeoFOR Using Retrospective Decomposition Data

Victoria Eacott, BA, University of Tennessee, Knoxville, Knoxville, TN; Sydney Munkus, BS, University of Tennessee Knoxville, Knoxville, TN; Tempest D. Mellendorf, MS, University of Tennessee, Knoxville, Knoxville, TN*

Learning Objectives: This presentation will inform attendees about the novel Postmortem Interval (PMI) estimation software, geoFOR. It will present an analysis of the software's accuracy in estimating PMI using retrospective photographs of decomposition. The study evaluates prediction accuracy across different seasons of deposition.

Impact Statement: This presentation will impact the forensic science community by demonstrating the current applications, reliability, and limitations of geoFOR, with emphasis on seasonal variability. Additionally, this study underscores the practical applicability of using retrospective forensic photographs for PMI estimation. By doing so, it aims to catalyze further discussion and innovation in PMI estimation methods.

Abstract Text: GeoFOR is an ArcGIS-based survey platform that utilizes a mass collaboration model for data collection. It integrates geospatial data with weather data and Machine Learning (ML) to generate PMI predictions for users. The current ML model is trained on over 3,200 cases, including retrospective death reports, forensic investigations, and longitudinal observations.[1-3]

This study utilizes a random sample of retrospective photographic data from donors at the Anthropology Research Facility (ARF) at the University of Tennessee, Knoxville, to evaluate the accuracy and precision of PMI predictions generated through geoFOR. Observations were recorded from donors and scored within the software to assess performance. This approach allows for broader trend analysis—particularly in examining accuracy across seasons—and investigates the potential of using forensic scene photographs to estimate PMI via geoFOR.

Donor photos from 2017 to 2024 were used, with 50 donors randomly selected and evenly distributed by season of deposition: 12 in fall, 13 in spring, 13 in summer, and 12 in winter. A pilot study using two donors per season was conducted to capture the average duration of each decomposition stage and to identify a midpoint for each stage by season. These were used to determine appropriate sampling days, with approximately four sampling days per case to capture all decomposition stages: fresh, active, advanced, and skeletonization. Decomposition stages were defined following Megyesi et al. and Bass.[4,5] Due to the variable progression of decomposition, some sampling days were adjusted to ensure complete representation of each stage. In total, 199 geoFOR PMI predictions were conducted.

Results indicate relatively high accuracy in PMI prediction for fall and spring, with respective success rates of 81.40% and 78.18% of known PMIs falling within predicted ranges. In contrast, accuracy declined in seasons characterized by extreme temperatures, with summer and winter showing rates of 57.14% and 43.18%, respectively.

Discrepancies between donors' Date Of Death (DOD) and Date Of Placement (DOP) were examined to assess their impact on geoFOR-predicted PMI estimates. Temporary storage—primarily coolers, and occasionally freezers—was evaluated for its ability to delay decomposition and align PMI more closely with DOP. Using DOD resulted in a 25-50 day average overestimation, generally not statistically significant ($p = 0.0736$ for fall; $p = 0.0005$ for spring; $p = 4.94e\text{-}05$ for summer; $p = 0.0736$ for winter). In contrast, DOP significantly reduced overestimation overall ($p = 0.0001$ for fall; $p = 0.0059$ for spring; $p = 0.0949$ for summer; $p = 0.0001$ for winter), supporting its use for more accurate PMI predictions. These findings indicate that donors stored under conditions that slow decomposition can serve as reliable proxies for PMI estimation when DOP is applied.

Future research will be necessary to examine error rates not only for predicted PMI ranges, but also for specific point estimate PMI dates. Furthermore, analysis will compare accuracy across decomposition stages.

This study provides valuable insight into the current effectiveness and limitations of geoFOR as a novel PMI estimation tool, highlighting both its potential applications and areas for improvement.

A120 Adipocere Formation in a Subtropical Climate and the Most Effective Method to Process Adipocere on Skeletal Remains

Amanda Schultz, BA, USF, IFAAS, Bushnell, FL; Erin H. Kimmerle, PhD, IFAAS, USF, Tampa, FL*

Learning Objectives: Upon reviewing this poster, attendees will gain a deeper understanding of the types of environments in which adipocere is commonly found. Attendees will also understand which processing methods are best suited for adipocere while maintaining the integrity of the bone.

Impact Statement: Examining the diverse burial conditions in which adipocere has formed will help contribute to the limited body of work that exists on the topic of adipocere. Cool, wet environments are typically described, yet this study explores the variation observed in hot and sub-tropic environments. Knowing how to clean adipocere most efficiently and effectively while maintaining the integrity of the bone can be beneficial when processing forensic cases that have adipocere. The following study offers best practice recommendations on a topic with virtually no standards and limited information.

Abstract Text: Adipocere is a "grayish-white, waxy, soap-like substance, produced from the decomposition of adipose tissue, which converts adipose tissue into triglycerides, fatty acids, and other products."[1] While adipocere is easily recognized, its formation and how to process it, are poorly understood.

The body of literature on adipocere considers cold, wet environments but does not include varied environments such as the subtropics with significant wet/dry seasonal shifts. Only a single case study provides any discussion of adipocere formation in a dry environment.[2] Other research has examined whether the presence of clothing or coffins affect adipocere formation and the rate of adipocere formation when buried directly in soil.[2-5] There is a lack of research on how to effectively process adipocere from skeletal remains, the varied conditions in which it forms, and the rate of adipocere formation.

The purpose of this study is to investigate the specific burial conditions and timing of adipocere formation. The second goal of the study is to provide best practice recommendations for processing adipocere to effectively recover skeletal tissue without damage and to best achieve results when testing for DNA, considering neither heat nor chemicals can be used.

Data was collected from the University of Southern Florida Donated Skeletal Collection at the Institute for Forensic Anthropology and Applied Science. The sample used includes 108 donors who were buried between 2017–2022 in a variety of burial conditions, including: (1) on the ground surface in direct sunlight (70%); (2) submerged in wet vernal ponds during the rainy season (6%); and (3) buried in shallow graves, directly into the soil at less than 1 meter (15%). Among the total sample, 36% (n=42) of donors placed at the facility developed adipocere. A severity scale was created; minor severity represents 5–25% of elements with adipocere, moderate severity represents 25–50% of elements with adipocere, and severe cases have over 51% of the elements covered in adipocere. It was determined that 47% of all donors were placed or buried during the wet season (June–November). Of the 42 individuals with adipocere present, 64% (n=27) were placed during the wet season. Among the donors that were buried, 79% (n=11) of them had adipocere. The findings of this study demonstrate that adipocere can occur in highly variable burial contexts, including on the surface in hot dry climates, but is most frequently found in wet, subsurface, burial contexts.

This study also tested multiple methods for processing adipocere from skeletal remains while maintaining the integrity of the bone in good condition and safeguarding future DNA testing. This study also tested numerous processing chemicals in a crockpot on medium heat. The chemicals that were tested are Dawn dish detergent, Terga Zyme, Ecos laundry detergent, and plain water without additives as a control on medium heat. The same bone (a thoracic vertebra) was used from the same donor for all three chemicals being tested for this study. This study has found that Ecos laundry detergent is the most effective and efficient method to process adipocere from skeletal remains.

A121 The Decomposition of Buried Human Remains in a Semi-Arid Environment

Alexander J. Smith, BA, Colorado Mesa University, Grand Junction, CO*

Learning Objectives: After attending this presentation, attendees will understand how the unique environment of western Colorado impacts the presentation and rate of human decomposition in shallow graves.

Impact Statement: This presentation will impact the forensic science community by contributing data and examples of decomposition in shallow graves that can inform Postmortem Interval (PMI) estimations in semi-arid environments.

Abstract Text: The estimation of PMI is an important component of death investigations.[1] There are many ways to approach PMI estimation, including analyzing the stage of soft tissue decomposition. While there are published studies on human decomposition on the ground surface, with the remains fully exposed to a variety of environments, studies relating to buried human remains are more limited.

The decomposition of buried remains is generally considered to be slower than decomposition on the ground surface in the same environment.[1,2] The difference in rate of decomposition is often attributed to the lower temperature underground relative to the surface, limited insect access to the remains, limited or no involvement of larger scavengers, and the formation of adipocere.[1-5] The rate of decomposition in burials is further influenced by the depth of the grave, with deeper graves further slowing the process, and the presence of clothing or wrappings.[2-4,6]

The Forensic Investigation Research Station (FIRS) at Colorado Mesa University is situated in a cool, semi-arid steppe climate. This environment causes human remains on the surface to desiccate early in decomposition, leading to substantial retention of mummified tissue years after death. The decomposition of buried human remains has not previously been studied in this environment.

Five human donors at the FIRS were buried in shallow, hand-dug graves between April 2014 and January 2024. All donors were White males aged 58-87 years at death. All burials were left undisturbed and recovered after a PMI between 1.6-7.2 years (566-2612 days).

Donors 1 and 2 (7.2 and 5.8 years, respectively) were both skeletal with minimal mummified tissue remaining at recovery. Donor 3 (3.8 years) was mostly skeletal with mummified tissue remaining on one side of the body. Donors 4 and 5 (2 and 1.6 years, respectively) retained significant amounts of mummified tissue and some grease at recovery. Some skeletonization was present on the arms and chest for both donors. Donor 3 had large collections of blow fly pupal casings on and inside the remains, indicating more significant insect activity than observed in the other four burials.

Contrary to published studies, donors buried at the FIRS generally reached more advanced stages of decomposition and skeletonization sooner than their counterparts placed on the surface. When compared to donors on the surface with equivalent or longer PMI, buried donors had less remaining mummified tissue. This was most apparent in Donors 1, 2, and 3 (most significant skeletonization) as donors on the surface generally still retained a significant amount of mummified tissue covering most or all the body at a similar PMI. For Donors 4 and 5, the differences were less significant, with the buried donors having only slightly less remaining mummified tissue than those placed on the surface.

The presentation and rate of decomposition for both buried and surface remains is heavily dependent on environmental variables. Understanding how the burial environment influences decomposition will improve methods of PMI estimation.

A122 Dirt, Decay, and Dentition: Taphonomic Alterations to Teeth From Buried Skeletal Remains in Southwest Florida

Emmalee Bullington, BS, Florida Gulf Coast University, Dade City, FL; Micki Besse, MS, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University, Fort Myers, FL; Savanna Agilar, MS, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Jeffery Kleeger, PhD, Florida Gulf Coast University, Fort Myers, FL; Shawn Keller, PhD, Florida Gulf Coast University, Fort Myers, FL*

Learning Objectives: Attendees will learn more about the impacts of soil staining and interment on estimations of age at death using single-rooted teeth, including an emphasis on calcium carbon-rich soil.

Impact Statement: This research impacts the forensic community because dentition is often regarded as a durable component to the skeletal system with regard to degradation over time. However, this study found that the single-rooted teeth were susceptible to taphonomic changes inhibiting age-at-death estimations in forensic anthropology contexts using existing methodologies.

Abstract Text: The Lamendin method for estimating adult skeletal age-at-death applies measurements of tooth root transparency, periodontitis, and root length to a regression equation.[1,2] Existing research found increased error rates when this method was applied to a cemetery burial context in Milan, suggesting considerations for the applicability of the methodology to forensic anthropological casework involving burial contexts.[3] These similar findings were observed in archaeological contexts citing potential impacts of geographic location, burial substrate, and duration of burial on the utility of the method.[4] Following American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 133 for age estimation in forensic anthropology, consideration must be given to the quality of the skeletal material used in the estimation of skeletal age-at-death.[5] In accordance with this standard and to gauge the suitability of estimating age-at-death from dentition impacted by taphonomic change, additional research is warranted to validate the efficacy of the existing method to encompass dentition from interred contexts in Southwest Florida. This study aimed at addressing this gap using a sample (n=10) of anatomical gift donations interred at Florida Gulf Coast University's Buckingham Environmental Forensics Facility (BEFF) and commensurable control group of Human Identity and Trauma Analysis (HITA) anatomical gift donations processed through traditional maceration methods.

This study superimposed site-specific data (i.e., Munsell Color Book, pH, temperature, and moisture) to further examine the taphonomic changes for each individual. Prolonged exposure within the moist, calcium carbonate-rich soils produced discoloration of the roots and adjacent alveoli containing the dentition. Consistent with the original method, this study revealed an average error rate of 6.67 years for the control group. In contrast, these data revealed an average error rate of 16.24 years for the experimental buried group—exceeding the acceptable error threshold established from the original method. These findings were also present when applied to the Prince and Ubelaker method. As applied to both methods, the error rates for buried remains exceeded those observed in the control sample and this positively correlated with duration of interment for the Lamendin ($r = 0.471$; $p = 0.009$) and Ubelaker methods ($r = 0.401$; $p = 0.028$). These findings were consistent with former studies and cautioned the forensic anthropologist to consider the discovery context when applying these methods in forensic casework and in comportment with existing forensic anthropology standards.

A123 Evaluating the Total Body Score (TBS) Method to Assess Performance of PMI Estimates in Forensic Casework

Katherine E. Weisensee, PhD, Clemson University, Clemson, SC; Madeline M. Atwell, PhD, Clemson University, Clemson, SC; Hudson Smith, PhD, Clemson University, Clemson, SC*

Learning Objectives: After attending this presentation, attendees will learn how the TBS method performs across a large and diverse dataset using data from previous forensic publications. This presentation will provide an understanding of the expected performance of this commonly used method for estimating the Postmortem Interval (PMI). This analysis supports transparency and interpretability when integrating TBS into PMI estimates in forensic applications.

Impact Statement: This presentation will impact the scientific community by demonstrating how the TBS method performs based upon a resulting R2 using a large and geographically diverse dataset (n=1,427) to provide a more realistic understanding of the accuracy of PMI estimates using the TBS methodology.

Abstract Text: Time since death, or the PMI, is considered a crucial component of medicolegal death investigations. A reliable PMI estimate can contribute to positively identifying unknown human remains and reconstructing perimortem timelines surrounding suspicious and unwitnessed deaths. Despite decades of research resulting in a vast body of PMI inquiries and methodologies, one method continues to be frequently applied and researched: TBS.[1] The TBS method gained considerable traction within the discipline of forensic anthropology after its publication in 2005 and is still commonly employed today, as evidenced by nearly 800 citations in Google Scholar. Our presentation will provide an evaluation of the TBS method from a compilation of published data (n = 1,427). We also provide an updated r2 to give insight into the expected performance (MA1) of TBS as a method for estimating ADD and PMI across a range of death and decomposition scenarios.

We conducted a search for peer-reviewed literature, master's theses, and doctoral dissertations to identify published TBS and ADD data to include in our analysis. The dataset compiled includes 11 publications with TBS and ADD data, five of which are peer-reviewed in academic journals. The remaining six studies are master's theses (n=3) and doctoral dissertations (n=3). The resulting dataset from this compilation involved observations (n=1,427) of 456 human cadavers from experimental longitudinal studies at human decomposition research facilities, as well as cases from medicolegal death investigations (MA2).

The results of our analysis using a large and geographically diverse dataset demonstrate that the model performance of the TBS method has an r2 value of 0.39 for the regression formula logADD vs. TBS2, which is less than the original finding of 0.84.[1] Furthermore, more recent research has also demonstrated a mathematical error in the original TBS formula.[2,3] When the corrected TBS formula provided by Smith et al. is applied to the larger dataset, the TBS model performance is only slightly improved, with an r2 value of 0.45.[3]

In our initial examination of the dataset, we observed systematic effects of the model fit across publications. In order to explore these effects, we trained multiple models on all but one of the studies and used the holdout study to examine how well the models performed. This provides a more robust way to see how the model generalizes in different settings. This analysis found overall poor performance of the model with an R2 of -0.58; this value was influenced by an outlier that skewed the data. When accounting for the outlier, the median R2 is 0.04.

The results of our analysis demonstrate that the TBS model does not generalize well across different decomposition settings, and the actual model performance is lower than previously reported by Megyesi and colleagues.[1] The TBS method sums the complex process of decomposition into a single value with 32 possibilities, which does not provide reasonable performance in the field based on our results.

A124 Investigating the Applicability of Different Postmortem Interval Estimation Methods in the Mid-Atlantic Region

Mason Kalin, George Mason University, Fairfax, VA; Kennedie A. Lyles, BS*, George Mason University, Woodbridge, VA; An-Di Yim, PhD, George Mason University, Manassas, VA; Emily D. Rancourt, MSFS, George Mason University, Manassas, VA; Molly Kilcarr, BS, George Mason University, Springfield, VA; Chloe R. Cummings, BS, George Mason University, Fairfax, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the different Postmortem Interval (PMI) estimation methods. The attendees will understand which PMI estimation method is the most applicable in the Mid-Atlantic Region.

Impact Statement: This presentation will impact the forensic scientific community by demonstrating the pros and cons of different PMI estimation methods as they apply to casework in the Mid-Atlantic Region. This is the first study in this region that used an actualistic experimental design to answer a practical question regarding PMI estimation.

Abstract Text: PMI or time-since-death estimation relies on assessing the stages of decomposition to provide a range for how long an individual has been deceased. Previous studies showed that the rates of decomposition are highly variable and region-specific. While there are different PMI estimation methods available, none of these methods were tested for the Mid-Atlantic Region, and their applicability to casework is unknown. This study evaluates five PMI estimation methods to find the most applicable method for the Mid-Atlantic Region.

Eight donors from the George Mason University Forensic Science Training and Research Laboratory were used for this study, totaling 262 instances of documented decomposition changes and known PMI. Decomposition changes for each donor were scored by 20 undergraduate and graduate students using Megyesi's Total Body Score (TBS).[1] Each donor's decomposition progression was observed for at least 21 consecutive days, followed by weekly and monthly documentation. Qualitative and quantitative data were compiled along with photography. The TBS were then converted into Accumulated Degree Days (ADD) using the Megyesi methodand the Moffat and Smith revisions.[1-3] Estimated ADDs were then converted into PMI. In addition, all instances were scored using Vass and geoFOR parameters by the first and second author retrospectively using photographs.[4,5] PMI estimates were then derived using the Vass equation as well as the geoFOR web application.

Preliminary results showed that Smith's revised equation provided the most accurate estimation of PMI when compared to the actual PMI. This was followed by geoFOR. The original Megyesi equation had a similar accuracy rate as the Moffat revision (approximately 36-43% of time), where the actual PMI fell outside the predicted range. The Vass equation showed similar results to the original Megyesi and the Moffat revision, while geoFOR was slightly more accurate than the three equations. As expected, the predicted intervals produced by all methods become progressively wider as decomposition progresses. Notably, desiccation was consistently observed, which may obscure or introduce inaccuracy/bias to PMI estimation for this region. Further research will continue to monitor the trends observed in this study for the Mid-Atlantic Region.

A125 Saturated (Equatorial) Savanna Soils: The Efficacy of Anaerobic Postmortem Interval Estimations in Southwest Florida

Savanna Agilar, MS, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, MS, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University, Fort Myers, FL*

Learning Objectives: After attending this presentation, attendees will have learned the influence of soil temperature and moisture in the estimation of anaerobic Postmortem Interval (PMI) estimations in an equatorial savanna climate.

Impact Statement: This presentation will impact the forensic science community by identifying the variables that may influence the efficacy of anaerobic PMI estimation in southwest Florida and inform forensic anthropologists of the practicality of utilizing these PMI methodologies in an equatorial savanna climate, which supports a back-to-basics approach to understanding the impact of savanna soils on PMI.

Abstract Text: Existing anaerobic PMI estimations rely primarily on the Vass methodology, which is currently the only empirically developed model for buried remains.[1] This approach calculates PMI based on estimated soft tissue decomposition, soil temperature, soil moisture, and the extent of adipocere formation.[1] Notably, however, the dataset which informs Vass' novel methodology is regionally limited to the humid, warm temperate climate of Tennessee.[1,2] Previous research that evaluated the applicability of Vass' anaerobic PMI estimation method in a northern geographical region found the equation to be ineffective at obtaining an accurate PMI estimate—suggesting impracticality of applying an equation developed in a region with extreme climatic differences.[3] Comporting with American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 149 for taphonomic observations in support of the PMI, a validation study is warranted to evaluate the efficacy of applying Vass' Universal PMI equation to the sandy soils of an equatorial savanna climate in southwest Florida.[2,4]

Decomposition rates may be impacted by myriad factors, though research has found that soil moisture is one of the primary environmental influences. Specifically, with temperature held constant, the literature reveals that decomposition is slower in both very dry and very saturated soils. [1,5] In this study, we investigated the applicability of the Vass equation in southwest Florida sandy and saturated soils and supplement existing anaerobic PMI studies by examining soil temperature and moisture variables relative to anaerobic PMI estimation using three anatomical gift donations interred at Florida Gulf Coast University's Buckingham Environmental Forensics Facility (BEFF).

As an alternative to the subsurface thermocouple temperature instrumentation used in previous studies, we collected anaerobic soil data using HOBO MX2300 data loggers with soil temperature and moisture probes installed within each of the burial vaults at the time of interment. For each burial, we averaged 1-minute-interval soil temperature (C°) and moisture (m^3/m^3) data from interment through exhumation. Following the Vass method, we calculated PMI for each of the burials and compared estimates to the known duration of interment values to assess reliability. The data revealed that the lower threshold of the estimation range produced a more reliable PMI for all three burials. Notably, however, the burial with more saturated soil moisture (38%) overestimated PMI and produced the highest average error (-76 days), while those with less saturated soil (6% and 12%) effectively estimated PMI with only -23 and -28-day average error. Consistent with existing literature, a strong negative correlation (r = -0.820) was observed between soil moisture and PMI estimation where the estimated PMI decreased in duration as moisture increased—though the small sample size precluded statistical significance. This pilot study supported the potential efficacy of Vass' Universal PMI anaerobic equation as applied to human remains burials in southwest Florida by yielding accurate PMI values in two out of three experimental burials. The results of this study underscore the necessity of comportment with ANSI/ASB Standard 149 and emphasize the need for trained practitioners to consider the depositional environment and the ecological factors which influence decomposition when applying and interpreting PMI estimation methods.

A126 The Need for Additional Environmental Diversity in Human Decomposition Research Facility Locations

Rachael S. McCrary, MS, Ohio State University, Columbus, OH; Nicholas V. Passalacqua, PhD, The Ohio State University, Hilliard, OH*

Learning Objectives: Attendees will be able to: (1) describe a mesoclimate and explain how mesoclimates can vary across the same macroclimate; (2) explain how mesoclimates and population density are relevant to human decomposition research, and (3) understand the need for additional environmental diversity in human decomposition research facility locations based on mesoclimate and population density data analysis.

Impact Statement: This presentation will impact the forensic community by demonstrating the need for additional human decomposition facilities across the United States and abroad based on variations in mesoclimates, urbanization, and scavenger guilds.

Abstract Text: While the first human decomposition facility was created over 40 years ago in Knoxville, TN, today there are only 14 in operation globally, 12 of which are in the United States. Having a vast array of climates nationwide as well as a number of universities housing forensic anthropology programs, the United States is an excellent area to study taphonomy and human decomposition, though it lacks facilities in many regions, including the urban Midwest.

According to the Koppen–Geiger climate map, 9 of the 12 United States decomposition facilities are in the same overall climate zone (Cfa – temperate with no dry season).[1,2] However, this does not take mesoclimates into account, nor does this account for population density. Mesoclimates are defined as a "city-scale climate" and take into account more local features such as altitude and urbanization.[3] Population density is also relevant to decomposition facilities because scavenger guilds differ in urban vs. rural areas.[4] This begs the question: is there a difference in mesoclimates and population density across the nine Cfa-zoned cities that have decomposition facilities? If so, do those mesoclimates and population densities differ from an urban Midwestern city (in this case, Columbus, located in Frankin County, OH).

To test this, local temperature and precipitation data from the past 50 years were sourced from digitally available weather stations, and population density was measured using census information by county for the years 2010-2019. When running Kruskal-Wallis tests to compare average temperature data across the nine cities and Columbus, OH, all were statistically different from each other (adj. $p < 0.02$) except for one instance. Precipitation comparisons generated similar results, with all cities being statistically different than one another ($p < 0.001$), except for two cities. When comparing population density, of the 45 pairwise comparisons, 20 were statistically different ($p < 0.05$) and 5 of those 20 involved comparing Franklin County, OH, to another county. Meaning, the Franklin County population density is significantly different from 5 of the 9 counties containing decomposition facilities in this climate zone.

These results demonstrate high variation in mesoclimates. Even facilities that are within the same overall Cfa-climate are different from one another on a mesoclimate scale. Based on these results, there is a need for additional decomposition facilities across various locations in the United States (and abroad) to investigate human taphonomy and climate-specific estimations of the postmortem interval. Additionally, the urban Midwestern United States has a unique mesoclimate that could produce uniquely informative taphonomy research, while also serving as a centrally located midwestern hub for education and training in forensic anthropology, forensic archaeology, and taphonomy.

A127 A Camera Trap Analysis of Songbird Scavenging Behavior at the Anthropology Research Facility (ARF) - University of Tennessee, Knoxville (UTK)

Owen VanAntwerpen,, BS, Northern Michigan University, Marquette, MI; Hayden S. McKee-Zech, PhD, Northern Michigan University, Marquette, MI; Cory Elowe, PhD, Northern Michigan University, Marquette, MI*

Learning Objectives: Attendees will gain insight into the underexplored role of songbirds in carrion ecology through a case study using camera trap data from a human decomposition facility. This presentation will demonstrate how consistent provisioning of human donors as a resource affects scavenger behavior and explore implications for both avian ecology and forensic research contexts.

Impact Statement: This research broadens the understanding of faunal interactions with human remains by documenting and characterizing songbird scavenging behavior—an interaction rarely considered in forensic contexts. By leveraging consistent observation at a human decomposition facility, the study provides data that may inform taphonomic interpretations, particularly in outdoor scenes where avian activity could alter soft tissue decomposition or disarticulation patterns. These findings highlight the need to account for a wider range of scavenger species in forensic casework and may prompt revisions to current assumptions about postmortem interval estimation and scene reconstruction in avian-active environments.

Abstract Text: Though much is known about the use of carrion by birds that specialize in scavenging, the use of these resources by songbirds has not been well characterized.[1] Due to the highly ephemeral and unreliable nature of carrion in natural settings, these interactions tend to be opportunistic and difficult to observe.[2,3] Outdoor forensic research facilities allow for human donors to be made consistently available, with intensive observation of environmental variables and all aspects of the decomposition process at frequent intervals.[4] These facilities provide an opportunity to test the effects of consistent provisioning of a usually pulsed and ephemeral resource, as well address the unique impacts of human donors as a resource.

Through the analysis of images from camera traps set at the locations of five donors that were placed supine unclothed on soil surface at the UTK's ARF, this project aims to characterize songbird utilization of human donor resources. The nature of this unique interaction may have implications for understanding the behavior and ecology of the bird species involved, as well as for better understanding their role in carrion ecology and identifying future areas for further research. Our preliminary analyses show statistically significant trends in both diel patterns of visitation, and visitation across Accumulated Degree Hours (ADH). We hypothesize that this is related to arthropod abundance across stages of decomposition. However, images of European Starlings carrying larvae and even feeding them to juveniles suggests that donor resources may support breeding birds and will be an important aspect to explore moving forward. This research enhances forensic taphonomy by revealing that songbirds, previously overlooked in decomposition studies, can interact with human remains in measurable and patterned ways—potentially influencing tissue loss and postmortem interval estimations at outdoor death scenes.

A128 Assessing the Influences of Burial Environment and Season of Interment on Fetal Pig (*Sus Scrofa*) Decomposition in Western Pennsylvania

Dakota L. Dickerson, MA, University of Florida, Gainesville, FL; Alexandra Schmidt, BA, Indiana University of Pennsylvania, Homer City, PA; Andrea Palmiotto, PhD, Indiana University of Pennsylvania, Indiana, PA*

Learning Objectives: After attending this presentation, attendees will understand how fetal pig proxies, lacking microbial gut contents, decompose compared to established expectations from adult specimens and how burial environment and season of interment impact the decomposition process.

Impact Statement: This presentation will impact the forensic science community by highlighting limitations when using fetal pig specimens for decomposition studies, demonstrating how burial environment can significantly impact decomposition rates, and identifying how season of interment impacts the decomposition process. Modifications to traditional scoring methods are recommended when assessing fetal remains. The results of this study support estimation of the postmortem interval of fetal remains in forensic contexts for buried or surface remains in cold and warm months. Additionally, the presentation introduces a non-human research station in western Pennsylvanian that is available for forensic training and research.

Abstract Text: Decomposition rates are crucial to accurately estimate the Postmortem Interval (PMI) of remains in forensic investigations. The PMI is used to estimate the time since death, which can aid forensic investigators in understanding incident contexts, reconstructing postmortem environments, and evaluating alibis. However, decomposition rates vary regionally, and other factors affect decomposition processes, such as age and health of decedent, burial placement, scavenger activity, and weather.[1-3]

Despite some differences, researchers often use pig (*Sus scrofa)* proxies in decomposition studies.[4,5] Pig cadavers have similar internal organ structures, are more readily available, and face less strenuous ethical considerations, allowing for larger research sample sizes.

In September 2024, 15 stillborn pigs were situated on the Indiana University Of Pennsylvania (IUP) campus. Three pigs were situated on the ground surface and covered with wire mesh to discourage scavengers. The other 12 pigs were wrapped in wire mesh and buried ~30 cm below the ground surface. This same process was repeated in February 2025 with an additional 15 stillborn pigs. These two series were designated summer and winter series, respectively. For 30 days after each series, surface pigs were observed and photographed. After 30 days, three pigs from each series were exhumed and photographed. These pigs were then removed from the study. The exhumation process was repeated after 3 months, 6 months, and 12 months for each series until all 12 buried pigs were removed from the study. The surface pigs were observed on each occasion if present. Subsequently, the photographs were evaluated using scoring methods developed by Megyesi and colleagues and Keough and colleagues.[3,4] The daily scores for the surface pigs were evaluated using least squares regression, while the singular scores of the exhumed pigs were compared against the concurrent observations of the surface pigs.

The results of this study suggest that fetal cadavers do not follow the same decomposition patterns as older-aged cadavers. None of the 30 pigs within the study exhibited common characteristics such as bloating, rupturing of flesh with escaping decompositional fluids, or major skin slippage, which likely reflects the absence of gut biome activity. Based on these observations, scoring methods such as Megyesi and Keough are inappropriate for the estimation of PMI of fetal remains.

Additionally, significant differences in decomposition rates are observed based on the season of interment and burial environment. The summer surface pigs skeletonized within 8-11 days. Pigs that were buried decomposed more slowly than those on the ground surface. Conversely, after 42 days, the winter surface pigs were still fully fleshed with suggestions of mummification. During winter exhumations, several burials exhibited standing water, and those pigs displayed more advanced stages of decomposition than their drier counterparts.

This study demonstrates the value of considering age of decedent, season of interment, and burial environment when evaluating the PMI. Recommended modifications to the Keough and Megyesi methods for fetal remains include emphasis on sagging flesh, abdominal caving, and purging of fluids from cranial orifices, recognizing that fetal remains may not exhibit bloating or major discoloration.

A129 Investigating the Effectiveness of 3D Documentation of Taphonomic Changes

*Emily N. Powell *, George Mason University, Woodhaven, NY; Chloe R. Cummings, BS, George Mason University, Fairfax, VA; An-Di Yim, PhD, George Mason University, Manassas, VA; Emily D. Rancourt, MSFS, George Mason University, Manassas, VA; Marlowe Vaughn-Bueler, MS, GMU Forensic Department, Alexandria, VA*

Learning Objectives: After attending this presentation, attendees will gain a better understanding of the effectiveness of three-dimensional (3D) laser scanning in documenting taphonomic changes. Attendees will learn the accuracy of 3D imaging compared to photographic documentation and direct observation.

Impact Statement: This presentation will impact the forensic science community by demonstrating the accuracy of 3D scanning in documenting taphonomic changes. This technology can then be used in a legal setting to provide jurors with a better representation of the decedent at the time of discovery.

Abstract Text: Taphonomic changes are postmortem changes to the body from the time of death until discovery. It is important to accurately document these changes to provide an appropriate estimate of postmortem interval. 3D scans have been used before in documenting crime scenes and their benefits, such as providing an interactive scene map that can be used in a legal setting to provide a walk-through of crime scene, are well documented.[1] In recent years, smaller, hand-held 3D scanners allow the documentation of individual objects with intricate details within minutes. When applied to decedents in the forensic setting, the scans could allow the viewer to have a more realistic view of the body compared to two-dimensional (2D) representation provided through photographs.

A donor from George Mason University (GMU)'s Forensic Science Research and Training Laboratory was selected for this study. Taphonomic changes were recorded at regular intervals following direct observations using a quantitative scale, photographs, and 3D scans.[2] A Qualtrics survey was then created and distributed to GMU graduate students, medicolegal death investigators in the Commonwealth of Virginia, forensic anthropologists, and others within the field of forensic science. The survey consists of five sets of matching 3D scans and photographs in a randomized order. Participants were asked to evaluate taphonomic changes using the quantitative scale and qualitative stages.

A total of 30 individuals participated in the survey. Preliminary results showed that the inter-observer agreement for 3D scans and 2D photographs was similar (Weighted Cohen's kappa = 0.86 and 0.85, respectively). The intra-observer agreement for 3D scans and 2D photographs is high (Weighted Cohen's kappa = 0.91), suggesting 3D documentation can be used as effectively as 2D photographs to document taphonomic changes. Notably, both have a tendency for observers to over-score compared to the field scores. The results suggest that 3D scans should be used in combination with photographs in documenting taphonomic changes to ensure that the best representation of the decedent when direct observation is not feasible.

A130 Soil Types and Components That Influence Toolmark Retention for Forensic Archaeological Cases

Josephine A. Reid, BSc, Cranfield Forensic Institute, Charlottesville, VA; Roland Wessling, MSc, Cranfield Forensic Institute, Cranfield, England, United Kingdom; David Errickson, PhD, Cranfield Forensic Institute, Cranfield University, Shrivenham, England, United Kingdom*

Learning Objectives: Following this presentation, attendees will gain insights into a novel type of toolmark analysis research pertinent to cases involving clandestine graves as well as the apparent neglect of toolmark analysis in soil by researchers, despite its discovery and importance in many forensic cases. Attendees will also recognize the potential factors that may affect toolmark retention in soil and the need to investigate other factors not covered in this study.

Impact Statement: This project impacts forensic science by being one of the first instances of quantitative research completed on toolmarks found in varying soil types and compactions.

Abstract Text: In excavations of clandestine graves, toolmarks may be found within the cut of the grave. However, there is little to no data to explain why they are found or not, only qualitative observations from years of experience. Morse et al. concluded that, "It has been demonstrated that harder soil types, such as clay, can retain clear impressions of the tools used to originally excavate the grave."[1] The qualities of clay soils, potentially due to the size of the particles and their influence on plasticity, provide a potential answer.[2] However, without controlled, empirical research, it is not possible to say for certain.

In this research, three soil types were used across 18 tubs, for six grave contexts created per soil type. Six toolmarks were created in each grave context, from impressing a trowel into the cut in each tub. The grave contexts were then separated into interment lengths, either four- or eight-week periods, that the grave would be covered and then excavated. Two experiments were conducted, with the first having no compaction when backfilling, whereas the second did have compaction throughout backfilling. Therefore, a total of 108 toolmarks were created per experiment type, 36 toolmarks per soil type, then separated into two groups of 18 per interment length. Structured photographs were taken before and after interment to create photogrammetric 3D models using Metashape Professional software, for quantitative analysis using CloudCompare open-source software, which determined the distances between the cloud meshes. These values were collected for discussion on the results. Between both experiments, all of the toolmarks in the loamy sand and sandy loam soil types were found, whereas the clay loam soil type had 16.7% discovery in the first experiment and 38.9% discovery in the second.

In conclusion, there is not enough evidence to support the current literature and its conclusions on the toolmark retention longevity of "clay-rich" soils. There was little difference between toolmark recovery between interment lengths and that overall, compaction had a negative effect on the cloud-to-cloud comparisons, resulting in less similarity between the before interment and after experiment toolmarks. Future research into the influence of moisture, which affects the plasticity of clay-rich soils, and other components that impact malleability would better inform how toolmarks are retained in soil, allowing for the collection of all relevant evidence for casework.

A131 Utilizing pXRF to Resolve Unusual Discoloration in Cremains: A Case Study

Samantha M. McCrane, PhD, District 1 MEO & University of West Florida Anthropology Department, Pensacola, FL; Phoebe R. Stubblefield, PhD, CA Pound Human Identification Laboratory, University of Florida, Gainesville, FL*

Learning Objectives: After attending this presentation, attendees will be able to describe how Portable X-Ray Fluorescence (pXRF) may be utilized in the analysis of cremains to explain unusual discoloration as well as recognize what color changes may be expected from specific elements.

Impact Statement: This presentation will impact the forensic science community by enabling practitioners across subfields to better interpret pXRF results and staining in the analysis of cremains cases. This case study is especially key as these results directly contradict previously published findings on cremains staining.

Abstract Text: In recent years, cremations have come to make up a much larger percentage of body disposals, now comprising 61.8% of all funerary disposals in the United States.[1] Forensic anthropologists are often consulted to resolve uncertainties involving human cremains in criminal investigations, litigations against funeral homes, or private cases of bereaved families seeking closure. Requested determinations address the identity of a cremated individual, suspected commingling, or composition of cremains. As the powderization of cremains has become increasingly fine, chemical element analysis is an invaluable tool in cremains analysis for distinguishing osseous materials from cremation artifacts or contaminating substances and for ascertaining potential instances of commingling.[2-4]

This research explores a unique case of cremains analysis wherein the decedent's family was concerned that the composition of the ash contents was not human remains due to the inclusion of bright blue and green particles, as well as other non-white or off-white particles, interspersed throughout the ashes. The C.A. Pound Human Identification Laboratory was contracted by the family to determine the urn's contents. The examination employed visual assessment, radiography, and pXRF spectrometry in the analysis of this case. The pXRF results indicated copper, gold, silver, and platinum inclusions, best explained by an object (e.g., an electronic device like a cellphone or smart watch, or jewelry) accompanying the remains into the cremation retort. The blue and green particles were the result of copper staining.

This case furthers our understanding of cremains analysis because while copper staining on bone is well documented in forensic anthropology and archaeology, there is less consistency regarding color changes in cremains.[5-7] Most studies that have reported the presence of copper artifacts interred with human cremains either do not mention color changes, even when high levels of metals such as copper are detected via chemical element analysis, or refer to staining broadly without a description of the color observed.[3;8-10] Conversely, pink, green, and yellow coloration have been reported in cremains as the result of copper, iron, and zinc inclusions, respectively—results opposing our findings.[11] This case provides a recent example of how modern high-temperature cremations can rapidly oxidize a cremation artifact, leading to blue-green copper staining.

A132 The Persistence of Ultraviolet Bone Autofluorescence Following Submersion in a Corrosive Acidic Solution

Kendall Gehring, MA, California State University, Chico, Grayslake, IL*

Learning Objectives: This presentation will outline a novel application of an ultraviolet Alternate Light Source (ALS) bone fluorescence in a corrosive acidic environment, demonstrating that the method can be used to potentially locate human remains.

Impact Statement: After attending this presentation, attendees will gain a better understanding of the efficacy of ultraviolet ALS devices in detecting skeletal remains exposed to commercially available acidic corrosives for at least one week post-exposure. This is the first study to combine ALS fluorescence and chemical postmortem alteration to skeletal remains.

Abstract Text: Recent case literature, along with news reports and fictionalized media, indicate an accelerating frequency of postmortem alterations to human skeletal remains, including attempted chemical dissolution.[1] This is often in an attempt to conceal the commission of a crime or the identity of the victim. Exposure to acidic corrosive materials can pose an unusual challenge to forensic anthropologists who may then be tasked with locating and recovering incredibly friable skeletal material. Certain lab-grade acidic chemicals have even been demonstrated to totally consume some biological materials.[2]

ALS devices have been demonstrated to be valuable tools in the search for skeletal remains as type I collagen found in bone is naturally fluorescent; however, no study has tested their efficacy in cases where remains have been chemically treated. This study compares the persistence of bone autofluorescence under an ultraviolet ALS in both cortical and trabecular porcine bone samples exposed to a muriatic acid solution at one of two concentrations. A set of samples was also exposed to only tap water to account for submersion effects on bone autofluorescence.

The muriatic acid solutions were created using common household muriatic acid concrete etcher and tap water. The active corrosive ingredient is Hydrochloric Acid (HCl). It was hypothesized that a higher concentration of the active ingredient would lead to a more rapid destruction of bone collagen and thus a faster loss of sample autofluorescence. Changes in fluorescence were assessed by illuminating samples with an ultraviolet hand-held ALS with an excitation wavelength of 365 nm and photographing with a DSLR camera at 14 intervals over a period of seven days. Photos were analyzed using the software ImageJ according to a previously published method.[3]

None of the samples were found to totally lose bone fluorescence over the course of seven days. Average sample fluorescence intensity between the concentrated acid, dilute acid, and tap water trials was compared by Analysis of Variance (ANOVA) at each photo interval, with statistical significance noted in six intervals: 30 minutes ($p = 0.044$), 24 hours ($p < 0.001$), 48 hours ($p < 0.001$), 3 days ($p = 0.015$), 5 days ($p = 0.003$), and 7 days ($p < 0.001$). Though the overall trend was a decrease in fluorescence intensity as the submersion interval increased, the relative trend was variable between the three treatment groups. The results of this study indicate that ultraviolet ALS devices can still be used as aids in searching for skeletal remains, even if postmortem chemical alteration is suspected for timeframes of at least one week.

A133 Scattered Man: The Curious Case of Captain Henry Goodsell

Anna W. Delaney, DCrim, New Jersey State Police, Hamilton, NJ; Thomas A. Crist, PhD, Utica University, Utica, NY; Gina O. Hart, MA, Jefferson Parish Coroner's Office, Harvey, LA*

Learning Objectives: This presentation represents the collaboration between various agencies to help resolve a 181-year-old cold case. Several forensic methods were employed for the resolution of this case that include forensic anthropology, DNA, the Combined DNA Index System (CODIS), and investigative genetic genealogy.

Impact Statement: This presentation will demonstration how forensic anthropology assisted in the identification of an individual who died at sea 181 years ago off the coast of New Jersey.

Abstract Text: This presentation represents the dedication to finding missing individuals no matter how much time has passed since their disappearance. This case study began with forensic anthropology and concluded with the help of investigative genetic genealogy 181 years later. Remains were discovered off the coast of New Jersey in 1995, 1999, and 2013, and found in two separate counties. In each case, only select skeletal elements were found. A biological profile was developed for each case by three independent forensic anthropologists. All three cases arrived at the same conclusion with a similar biological profile.

At that time, there was no way to associate these remains to each other until a DNA profile was developed for each case. Profiles were developed by The New Jersey State Police Office of Forensic Sciences DNA Laboratory and The University of North Texas Center for Human Identification. Once the profiles were entered into CODIS, a genetic association was established and all three cases were consistent as belonging to the same biological male individual. The New Jersey State Police Office of Forensic Sciences Forensic Anthropology Unit worked closely with the New Jersey State Police Cold Case Unit to submit a sample for investigative genetic genealogy. The sample was processed by Ramapo College IGG Center where a lead was developed.

Investigative genetic genealogy is helping to resolve a plethora of cold cases throughout the country, and this is truly a remarkable case on how forensic anthropology can assist in historic remains. Captain Henry Goodsell finally has his name back.

A134 Exploring the Influence of Loading Direction on Fracture Characteristics in Human Tibiae

Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH; Christopher M. Goden, MA, Injury Biomechanics Research Center, Grove City, OH; Kyra E. Stull, PhD, University of Nevada, Reno, Reno, NV; Angela L. Harden, PhD, Injury Biomechanics Research Center, Columbus, OH; Julia C. McGinley, BS, The Ohio State University, Columbus, OH*

Learning Objectives: After attending this presentation, participants will gain insight into the effect of loading direction on tibial fracture characteristics resulting from blunt trauma. This research fills identified gaps in the current knowledge and methods of skeletal trauma research, analysis, and interpretation by providing controlled experimental bone trauma data focused on fracture mechanics to improve the validity and interpretation of skeletal trauma analysis.

Impact Statement: This presentation will impact the forensic science community by providing direct evidence of the relationship between fracture characteristics and loading direction in paired human tibiae loaded in the exact same loading conditions.

Abstract Text: Research exploring the role of loading direction on fracture outcomes in controlled laboratory experiments is limited. The few studies that do exist almost exclusively utilize animal (non-human) models, which presents significant challenges in translating findings to humans. For example, Cohen H. et al. identified a significant effect of loading direction on fracture patterns, but experiments were conducted on pig femora.[1] Therefore, the objective of this study was to investigate differences in fracture characteristics within pairs of human tibiae loaded from two distinct directions to explore the predictability of loading direction from observed fracture outcomes.

Ten tibia pairs from unembalmed adult postmortem human subjects were dissected from the leg and the proximal and distal ends were potted for testing. All tibiae were experimentally loaded to failure in a controlled 4-point bending test with blunt points of impact at 40% and 60% of bone length at 6 m/s. One of the paired tibiae, which was selected at random, was loaded in a Lateral to Medial (L-M) direction and the other tibia was loaded in a Posterior to Anterior (P-A) direction. All other boundary conditions were held constant between tests. Detailed specimen preparation protocols can be found in Harden A.L. et al.[2] Post-test trauma analysis included the identification of fracture type and group, and the number of fracture types per tibia, following the methods outlined in the AO/OTA Fracture and Dislocation Classification Compendium.[3]

No differences in number of fractures ($p=0.18$) or fracture types ($p=0.44$) were identified between tibia pairs in marginal homogeneity tests. Single fractures were more likely to occur in tibiae loaded P-A. Wedge fractures occurred more frequently in tibiae loaded L-M than those loaded P-A. Simple transverse fractures occurred only in tibiae loaded L-M, while longitudinal fractures occurred only in tibiae loaded P-A. Overall, fracture characteristics varied considerably within and between pairs suggesting a larger sample is necessary to clearly identify traits to assist with prediction of loading direction and may result in challenges with interpretation of blunt trauma in forensic casework.

Data from this research are organized into a publicly available Forensic Anthropology Skeletal Trauma (FAST) database, with the purpose of providing objective training resources for scholars and professionals to standardize trauma interpretations within and across disciplines.[4]

A135 Incomplete Kerf Morphology and Saw Class Characteristics: Comparative Statistical Insights From Fleshed and Defleshed Experimental Dismemberments

Stephanie J. Cole, PhD, Des Moines University, West Des Moines, IA; Heather M. Garvin, PhD, Des Moines University, West Des Moines, IA*

Learning Objectives: Following this presentation, attendees will have an increased understanding of how incomplete cut mark traits are statistically related to saw class characteristics to better inform cases of dismemberment.

Impact Statement: This research benefits the forensic science community by providing experimental data that explore the potential utility and limitations of incomplete cut traits in forensic anthropological interpretations involving dismemberment.

Abstract Text: Incomplete cuts produced during dismemberment may reflect saw characteristics such as tooth shape, tooth set, handle location, and saw power.[1-4] However, empirical support for these relationships is limited, and prior research often relies on defleshed bones stabilized in vices—conditions that differ from real-world forensic scenarios.[5] To address these limitations, this study evaluates statistical relationships between incomplete cut traits and saw characteristics using both fleshed and defleshed bone samples.

Traits and characteristics examined include: (1) Kerf Profile Shape (KPS) and tooth shape (crosscut or rip); (2) Kerf Length Shape (KLS) and tooth set (alternating, wavy, or raker); (3) Kerf Flare (KF) and handle orientation; and (4) Floor Dip (FD) and saw power (hand or mechanical). Fifteen hand and mechanical reciprocating saws were used to produce a total of 208 cuts: 130 defleshed cuts made with vice-stabilization and 78 fleshed cuts created through free-sawing to better replicate real-world dismemberment. Antimere limbs for defleshed and fleshed samples were used to control for donor variation. Chi-square tests with Bonferroni corrections assessed significance within and between samples.

In the defleshed sample, W-shaped KPS was exclusively associated with crosscut teeth (100%, $p< 0.01$), while non-W-shaped KPS was predominantly produced by rip teeth (96.4%, $p< 0.01$). Hourglass KLS was entirely associated with alternating sets (100%, $p< 0.01$). Necked KLS was primarily associated with wavy sets (83.3%, $p< 0.01$) and infrequently with alternating (5.6%) and raker sets (11.1%). Straight KLS was variable (alternating = 34.1%, wavy = 42.1%, raker = 23.9%) and was not a reliable predictor ($p=0.11$). KF was infrequently observed (25/126 cuts), but when present, occurred most often on the non-handle side (64%, $p< 0.01$), followed by the handle side (28%), and both sides (8%). FD rarely occurred (7/121 cuts) and was mostly associated with mechanical saws (85.7%), but significance was not attained ($p=0.21$).

In the fleshed sample, W-shaped KPS was again exclusively associated with crosscut teeth (100%, $p< 0.01$), and non-W-shaped KPS was almost always produced by rip teeth (98.3%, $p< 0.01$). Hourglass KLS was mostly associated with alternating sets (86.4%, $p< 0.01$), and infrequently with wavy (4.5%) and raker sets (9.1%). Necked KLS was primarily linked to wavy sets (87.5%, $p< 0.01$), occasionally with alternating sets (12.5%), and not observed with raker sets (0%). Straight KLS occurred more often with wavy than raker sets ($p = 0.025$), but the distribution remained too variable to be a reliable predictor (alternating = 35.4%, wavy = 47.9%, raker = 16.7%). KF was more common (27/73 cuts), again occurring primarily on the non-handle side (81.5%, $p< 0.01$), infrequently on the handle side (18.5%), and never on both sides (0%). FD was rare (2/62 cuts) and only seen with mechanical saws, but results were not significant ($p=0.49$).

Overall, the findings support existing literature, particularly the relationships between KPS and tooth shape and KLS and tooth set.[1,2] However, the results challenge expectations about KF location.[4] Although between-sample analyses did not reach statistical significance, nuanced differences suggest that fleshed, free-sawing experiments may better reflect real-world dismemberment and improve interpretations.

A136 The Resilience of Cut Mark Characteristics: A New Experimental Study on the Effect of Fire on Fleshed Remains

Mariah L. Morris, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Giada S. Steiger, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will better understand the impact of fire on fleshed bones and how it can negatively impact the analyses of cut marks.

Impact Statement: This presentation will impact the forensic science community by demonstrating a step forward in understanding how traits used to differentiate serrated from non-serrated knives in cut mark analysis can be altered by exposure to fire or cremation. The findings reveal that even when remains are initially protected by soft tissue, thermal alteration can compromise the reliability of cut mark interpretation, highlighting the need for updated protocols in fire-related forensic cases.

Objective: In forensic investigations of violent deaths, the analysis of cut marks on skeletal remains can provide crucial information about the weapon used and the nature of the attack. However, this analysis becomes particularly complex when the remains have been exposed to high temperatures, as in arson cases or fire-related accidents.

This study represents a further step from previous research that examined the resilience of cut mark characteristics on defleshed bone subjected to fire.[1] Here, we explore how the presence of soft tissue influences the visibility and survivability of these traits following thermal alteration.

Methods: Twelve porcine ribs (*Sus scrofa*) were used as human bone analogs. Ten cut marks were inflicted on each bone using a single-beveled, micro-serrated kitchen knife—identical to the implement used in previous experiments—to ensure consistency and because this type of blade reliably produces distinguishable and identifiable cut mark traits. Each cut was made with a single back-and-forth motion to simulate a stabbing action. The marks were examined using a low-powered stereomicroscope at 4.73–7.5x magnification and evaluated according to six traits previously proposed as diagnostic for identifying serrated versus non-serrated implements: (1) shape of the cut mark; (2) cross-profile shape; (3) rising; (4) feathering; (5) bone shards; and (6) mounding.[2] The ribs were divided into four groups and exposed to open flame for 5, 10, 20, or 40 minutes. Post-burning analysis was conducted using the same microscopic methods. In some cases, removal of remaining charred tissue was necessary, which was accomplished using a dermestid beetle colony.

Results: Results showed that fire exposure significantly degraded the cut mark characteristics. Rising, mounding, and feathering were the most vulnerable, often disappearing after brief exposure, consistent with previous results on defleshed bone.([1]) Cross-profile shape and bone shards showed moderate resilience but were often distorted by heat-induced fracturing. The overall shape of the cut mark, particularly when exhibiting a D shape, remained the most consistent and reliable trait post-exposure. Severe fracturing and fragmentation were observed in bones burned for 20 and 40 minutes. Two primary challenges affected the interpretation of cut marks: soft tissue often obscured or mimicked key traits prior to burning and post-burning alterations further complicated analysis.

Conclusion: This study demonstrates that cut mark characteristics are highly susceptible to destruction when remains, even if initially protected by soft tissue, are exposed to fire. However, certain features—such as the overall shape—exhibit greater resilience and can remain useful for analysis. The findings highlight the difficulty of examining cut marks on fleshed or partially burned remains and emphasize the need for further research into effective methods for exposing and documenting trauma when complete skeletonization is not present.

A137 Investigating the Utility of Micro-CT for Human and Non-Human Bone Compared to Traditional Histology

Rose Raymer, Middle Tennessee State University, Murfreesboro, TN; Laura E. Cirillo, PhD, SNA International supporting the Defense POW/MIA Accounting Agency, Omaha, NE; Savannah G. McAdow, MA, The Ohio State University, Columbus, OH*

Learning Objectives: After attending this presentation, participants will have a better understanding of the potential use of micro-Computed Tomography (micro-CT) technology to visualize human and non-human bone in place of traditional histology for differentiating human bone from non-human. Attendees will also learn the advantages and disadvantages of using a micro-CT and practical considerations for incorporating it into any laboratory.

Impact Statement: This research impacts the forensic science community by broadening the understanding of forensic applications of non-destructive micro-CT technology by demonstrating the ability to visualize characteristics that are diagnostic of human and non-human bone.

Abstract Text: The type, pattern, and organization of bone microstructures are analyzed in traditional histology methods to differentiate human bone from non-human osseous material. Micro-CT provides a non-destructive, time-efficient, 2D or 3D method for visualizing structures in osseous material. Previous studies have compared bone cellular structure between histology and micro-CT, but the existing literature lacks a practical comparison of the two modalities for a forensic context to differentiate human bone from non-human.[1-3] This project explores practical concerns of the use of micro-CT technology to visualize human and non-human bone as a potential replacement for traditional histology in a forensic laboratory setting and provides a cost-benefit analysis for typical forensic laboratories.

A sample of four human and six non-human femora (dog, goat, and lamb) were analyzed using both traditional histology slides and 2D slices from micro-CT scans (serving as the most analogous image to traditional slides). All samples were sourced from and analyzed at the Defense POW/MIA Accounting Agency. The human samples were derived from forensic casework and compared to non-human samples. Whole bones and cuts embedded in histological blocks of resin were compared for differences in visualization. All samples were scanned at 80 kVp and 100 µA using an aluminum filter, 0.15° rotation steps, frame averaging of four, and 180° rotation using a Bruker Skyscan 1273. Voxel size and integration time were adjusted for sample size and density. The 2D micro-CT slice images were compared to histology slides from a similar region on the diaphysis to compare visualizations of bone microstructures.

Each human sample exhibited Haversian bone tissue indicated by characteristics such as distinct Haversian canals and secondary osteons across modalities. Each non-human sample exhibited linear organization in plexiform bone and smaller visible canals in Haversian bone, when present, across modalities. The micro-CT images lacked visible detail for smaller structures such as the osteocyte lacuna-canalicular network; plexiform bone often appeared non-continuous or without a consistent margin, as visualized in the histology slides. Some micro-CT scans of non-human samples lacked detail in crucial components for confidently identifying non-human bone. Three of the six non-human samples (two dog and one lamb) exhibited clear plexiform bone across the majority of 2D slices and could easily be identified as non-human. The remaining three exhibited organization that is suggestive of plexiform but lacked the detail of the histology slides and consistency between slices to confidently identify them as non-human by all observers. Scans with better resolution may result in better visualization of these structures. There were no significant effects of resin embedding in visualization.

The major benefits of micro-CT visuals included the average total time (< 3 hours), the larger image set to capture the necessary structures in the correct orientation for analysis, and the flexibility of parameters to accommodate taphonomy and variation in density. Micro-CT scans of bone can reasonably be used to assess human vs. non-human in forensic contexts, or at least serve as a precursor to eliminate a backlog of histology analysis, but some adjustments are needed to achieve consistent details.

A138 Modeling Sharp Force Trauma: A Bayesian Approach to Differentiate Bone Surface Modifications From Straight and Serrated Blades

Alexander Cortes, BS, Arizona State University, Phoenix, AZ; Kymani SB Bledsoe, Arizona State University, Casa Grande, AZ; Jacob A. Harris, PhD, Arizona State University, Phoenix, AZ; William Nyce, Arizona State University, Phoenix, AZ*

Learning Objectives: After attending this presentation, attendees will be aware of a novel statistical method to accurately and objectively classify sharp-force skeletal trauma and identify the sharp implement used to generate cut marks on skeletal material.

Impact Statement: This presentation will impact the forensic science community by demonstrating the enormous potential of probability approaches to address complex topics that are prone to equifinality and inter-analyst subjectivity.

Abstract Text: Trauma from violent crime remains a persistent issue. According to the most recent National Violent Death Reporting System (NVDRS) published by the Centers for Disease Control and Prevention (CDC), 10.1% of homicides in the Unites States were committed with a sharp instrument. Similar reports from England, representing 40 years of data suggest 35% of homicides in the United Kingdom were committed using sharp implements. With homicide rates in the Unites States consistently between 6 and 8 per 100k and a global average of ~5.8, there is an increasing need for the ability to accurately identify the sharp implement responsible for trauma. Although previous studies in sharp force trauma dynamics suggest different blade types can leave qualitative differences in the associated Bone Surface Modifications (BSM) from serrated and straight-edged blades, the issue of equifinality, where two or more actions leave similar or even indistinguishable traces, persists.[1,2] To address this issue, we have constructed a formal discriminatory model to objectively differentiate agent of bone surface modification.

In the current pilot study, we build on previous research by extracting a suite of microscopic three-dimensional (3D) quantitative traits from a sample of experimentally generated BSM produced from similarly sized straight and serrated metal blades.[2] Individual cut marks were scanned using a 3D optical profilometer with 0.1micron resolution. BSM data were modeled within a Bayesian framework to produce a probability model of agent assignment and test the hypothesis; BSM from competing agents of modification can be accurately and objectively differentiated. Model output includes posterior distributions of shape attributes associated with each class of cut mark along with an assignment of probability for each blade type. We validated our model using a 10% out-of-sample cross validation subset of our data. The posterior results of our classification model, trained to differentiate BSM from two agents of modification, performed with an average success rate of 90%. These results support our hypothesis and highlight the benefit of extracting quantitative data and modeling these within a probabilistic framework.

A139 Chopping/Hacking Sharp Force Trauma on Bone: A Forensic Analysis of Cut Marks Using Macroscopic and Microscopic Techniques

Kelly C. McGehee, MA, University of Central Florida, Orlando, FL; John J. Schultz, PhD, Department of Anthropology, University of Kentucky, Lexington, KY*

Learning Objectives: Attendees will gain an understanding of how key macroscopic and microscopic cut mark characteristics are associated between and within six chopping/hacking tool classes using experimental and inferential statistical analyses. More specifically, this presentation will demonstrate an experimental research design of manually inflicted chopping/hacking trauma to partially fleshed pig long bones, combined with standardized methods and statistical strategies (e.g., chi-square, multiple correspondence analysis, clustering analysis, and multinomial logistic regression) to support future sharp force trauma studies.

Impact Statement: This presentation contributes to the ongoing refinement of sharp force trauma analysis by exploring the potential for differentiation both between and within chopping/hacking tool classes using macroscopic and microscopic cut mark characteristics. The standardized methodology and statistical approaches presented are intended to support greater consistency and comparability in future experimental research and forensic casework. By addressing current gaps in methodology and data analysis, this research aims to assist practitioners and researchers in developing more reliable interpretations of chopping/hacking trauma.

Abstract Text: Evaluating sharp force trauma injuries to bone inflicted by chopping/hacking tools (i.e., swords, axes, hatchets, machetes, and cleavers) is a growing area of research within forensic anthropology. Recognizing and understanding skeletal trauma characteristics from different sharp force tools allows forensic anthropologists to identify, or exclude, possible tool classes used. However, current experimental literature varies widely in methodology, materials, and analytical approaches, making comparison across studies difficult. The purpose of this research was to investigate the cut mark characteristics produced on pig bones (*Sus scrofa domesticus*) by six chopping/hacking tool classes, examining both macroscopic and microscopic features to determine if differentiation could be made between and within tool classes. This research seeks to improve the analysis of chopping/hacking trauma cut mark characteristics to determine the combination of macroscopic and microscope criteria for distinguishing tool class.

Trauma was manually inflicted to 48 partially fleshed pig hindlimbs using ten chopping/hacking tools (two from each class: axe, hatchet, machete, cleaver, and sword) and two carving knives for comparison. Limbs were placed in a standardized position with downward chopping/hacking force focused on the long bones. Following trauma infliction, tissue was removed via maceration. Each cut mark was analyzed for 16 macroscopic and 15 microscopic characteristics commonly described in forensic literature using direct observation and a digital microscope, respectively.

Statistical analysis using RStudio (version 4.5.1) included exploratory analyses (cluster analysis and Multiple Correspondence Analysis [MCA]) and inferential statistics (chi-square tests and multinomial logistic regression). K-modes clustering was applied to assess patterns among cut marks, with the number of clusters predefined as six based on the number of tool classes. As a result, clusters were generated based on combinations of cut mark characteristics. Notably, Cluster 3 (marked by characteristics such as macroscopic and microscopic edge and wall irregularity, flaking, chattering, and fracturing) corresponded closely with axes and hatchets, while Cluster 4 (characterized by unilateral cut mark edge damage) corresponded closely to machetes. Despite notable overlap, MCA provided visual support for pattern differentiation of cut mark characteristics, revealing trends in macroscopic and microscopic cut mark characteristics that correspond to specific tool classes. The chi-square tests yielded 29 statistically significant differences (15 macroscopic and 14 microscopic characteristics) between tool classes, with Cramer's V values indicating weak moderate effect sizes. These results suggest certain cut mark characteristics vary across tool categories. Statistically significant differences were also observed within tool classes, especially among axes, hatchets, machetes, and knives. These within-class associations more frequently involved microscopic features, indicating that micro-level analysis may assist in refining tool class differentiation. Multinomial logistic regression correctly predicted tool class in 46.63% of cases with accuracy rates ranging from 35.71% (knife) to 51.07% (axe).

This study demonstrates how experimental methodology combining macroscopic and microscopic analyses with statistical modeling can support differentiation between and within tool classes and strengthen forensic interpretations. While identifying specific tools remains difficult, certain cut mark characteristics may help differentiate between broader tool categories. This suggests the method has potential for supporting forensic anthropological interpretations and would benefit from further investigation.

A140 Standardizing and Re-Evaluating Observer Agreement in Kerf Traits Commonly Used to Predict Saw Class Characteristics

Ashley B. Maxwell, PhD, Washburn University, Topeka, KS; Alexandra R. Klales, PhD, Washburn University, Topeka, KS*

Learning Objectives: This presentation highlights inconsistencies in kerf trait interpretations and presents more standardized trait descriptions, illustrating to attendees how the use of these improved descriptions increases observer agreement.

Impact Statement: This presentation impacts the forensic science community by presenting measures of kerf trait scoring reliability in dismemberment cases and providing a list of traits with high inter-observer error for implementation in casework.

Abstract Text: Forensic anthropologists are frequently asked in dismemberment cases to assess kerf traits on the cut surfaces and provide information about the tool class characteristics and sawing process. To date, few studies have tested the reliability of scoring kerf variables in saw cuts and those that do are often limited to a single trait, have small saw or kerf samples, or use cuts made in defleshed, disarticulated bone, often of animal origin. These studies are unlikely to capture the range of kerf trait expressions that may be involved in forensic cases.

In 2022, we performed a pilot study examining the reliability of 13 kerf traits in a sample of 45 cuts, created with nine saws using a free-sawing method in fleshed, articulated, human cadaveric appendages and found that observer agreement was highly variable (46.7-92.3%).[1] Low agreement for many traits was due to inconsistent terminology, subjective interpretations, and limited exemplary images to guide scoring. Unreliable scoring could have significant legal consequences, as the misinterpretation of the scoring of these kerf traits could lead to erroneous tool predictions. As such, this research expanded the pilot study by creating standardized trait scoring procedures with multiple practitioners, and then re-assessing kerf trait inter-observer error in a new sample of 70 cuts made in a fleshed, cadaveric sample using a free-sawing methodology with 33 saws.

Trait definitions and images were compiled from the literature and group discussions involving eight researchers of varied experience levels were held to develop a standardized data collection scoring form. For each trait, the form included a detailed trait definition and scoring considerations. Several traits had both a simplified scoring system (e.g., present/absent) and an expanded version to include more descriptive representations. Two observers, not involved in the sample preparation (saw selection, cutting, or labeling), blindly scored 17 traits in complete (n=49) and incomplete (n=21) cuts using the bony specimens and associated silicone molds. Each observer examined all 70 cuts/molds macroscopically and microscopically using a digital 3D microscope. Absolute (%) agreements and *Kappa* (*K*) statistics were used to assess observer agreement, with *K* agreement interpreted as outlined in Landis and Koch.[2]

The standardized scoring procedure improved absolute agreement in 8/13 traits from the pilot study (breakaway spurs/notches, entrance shaving, harmonics, kerf flare, kerf profile shape, polish, and uniformity), but absolute agreement still varied widely by trait. Simplified scoring systems had higher agreement than expanded scoring systems. *Kappa* agreement was substantial to almost perfect in the simplified scoring system for breakaway spurs/notches, longitudinal fracturing, kerf length shape, exit chipping, kerf profile shape, harmonics, floor dip, and associated incomplete cuts. *K* was moderate for initial shaving, patterned kerf relief, paint transfer, polishing, pull-out-striations, and uniformity. Slight to fair agreement for entrance shaving, metal transfer, tooth hop, and tooth imprints suggests that caution should be used when scoring these traits in casework and, unless they can be further standardized, they should not be used to predict tool class characteristics.

A141 Crack Propagation in Projectile-Impacted Human Long Bones

Angi M. Christensen, PhD, FBI (Retired), Alexandria, VA; Mariyam I. Isa, PhD, Texas Tech University, Lubbock, TX; Brian Spatola, MA, National Museum of Health and Medicine, Silver Spring, MD; Timothy P. Gocha, PhD, Oklahoma Office of the Chief Medical Examiner, Tulsa, OK*

Learning Objectives: Attendees of this presentation will see how cracks propagate in human long bones following projectile impact, as documented using high-speed video. They will learn how the fracture sequence differs between entrance and exit sites and how it compares to that observed in crania.

Impact Statement: This presentation will help forensic anthropologists and pathologists in the analysis of skeletal trauma by providing new insight into how long bones fracture when impacted by projectiles.

Abstract Text: The purpose of this study is to document how cracks initiate and propagate in human long bones following impact with high-velocity projectiles (bullets) using high-speed video. Rather than interpreting fracture production based on final crack configuration and fragment shape, we directly observe fracture initiation and propagation.

Whole human long bones from ten cadaveric donors who had consented to traumatic analysis (one humerus, femur, and tibia per donor; n = 30 bones) were resected. Muscles, ligaments, tendons, and the periosteum were removed from the diaphysis, after which the long bones were frozen until testing. Each bone was shot with a 9mm full metal jacket bullet fired at a constant distance (~10 feet) and velocity (~1127 feet per second). Tests were carried out at the Federal Bureau of Investigation's (FBI) Ballistic Research Facility (BRF), where high-speed video was filmed at 55,000 frames per second using two cameras positioned at approximately 90 and 165 degrees relative to the projectile path. This setup allowed visualization of crack initiation and propagation at both the entrance and exit locations. Anatomical surface of impact was varied by test. Observations were made from both moving video and a standardized subset of still frames.

Most fracture sequences were complete within five to eight frames (91–145 µs), with the longest lasting ten frames (182 µs). Fracture propagation in femur impacts generally occurred over a longer duration than in the tibia or humerus, likely due to the larger diameter of the femur compared to the other bones.

Regardless of bone or anatomical surface impacted, the general crack sequence at the entrance site began with chipping at the impact site, followed by radial cracks propagating from the impact site, and then circumferential cracks forming between adjacent radial cracks. This pattern resembles that seen in projectile impacted crania. Crack initiation and propagation were typically more complex on the side of the bone opposite impact. Often, one or more longitudinal cracks formed before a distinct exit defect developed. Longitudinal cracks sometimes curved back toward the entrance, often intersecting entrance radial cracks. Transverse cracks sometimes formed between longitudinal fractures. Compared to crania, there appears to be greater interaction between entrance and exit cracks on projectile impacted long bones, possibly due to their smaller diameter. Long bone geometry and buttressing may also influence crack propagation.

Fragment reconstruction and fracture surface analysis may help clarify the mechanics underlying crack initiation and propagation, particularly at the exit location, which appears to behave differently in long bones than crania. A more thorough understanding of the crack propagation process will facilitate a more accurate interpretation of resulting fracture patterns in forensic skeletal trauma analysis.

A142 Classifying Projectile Entrances and Exits in Flat Bone: Insights and Challenges With Machine Learning

Mariyam I. Isa, PhD, Texas Tech University, Lubbock, TX; Delaney Edwards, MA, The Ohio State University, Columbus, OH*

Learning Objectives: Attendees will learn how fracture characteristics differ between projectile entrance and exit defects and how these variables perform in basic Machine Learning (ML) models for side prediction, including limitations related to caliber and observer effects.

Impact Statement: This presentation impacts the forensic science community by demonstrating entrance-exit differences that may inform projectile trauma analyses. It highlights the utility of ML for revealing the importance of and relationships among variables while showing that more basic analyses are important for understanding the factors influencing model performance under different conditions.

Abstract Text: Differences between entrance and exit side fracture characteristics were previously reported in projectile-impacted flat bones.[1] Building on these findings, this study examined side-specific relationships among fracture characteristics and then used Random Forest (RF) modeling to evaluate their utility for classifying projectile entrances and exits. This complementary approach provided context that strengthened interpretability of modeling results.

Objectives: (1) Characterize side-specific relationships among fracture characteristics to understand differences that may inform predictive modeling; (2) evaluate the utility of fracture characteristics for predicting defect side using RF models; and (3) assess model reliability (inter-observer variation) and generalizability (external experimental conditions).

Methods: The primary dataset (n=60) comprised porcine scapulae impacted with 9 mm Full Metal Jacketed (FMJ) bullets. Five observers scored entrance and exit fracture characteristics. Wilcoxon signed-rank tests and Spearman's rank correlations assessed relationships among fracture characteristics across and within sides. Four RF models (9, 6, 3, and 7 predictors, Models 1-4) were trained using an 80/20 training/holdout split optimized by Monte Carlo simulation (n=1000 seeds). Model accuracy was evaluated on the holdout set, across observers, and on an external dataset (n=30) of scapulae impacted with .308, .32, or .40 caliber FMJ bullets.

Results: Entrances had fewer cracks and crack types, longer individual cracks, and smaller, more symmetrical defects, while exits showed greater complexity, longer total fracture lengths, and larger, more asymmetrical defects. Apart from a weak correlation in maximum crack length, features did not correlate across sides, suggesting largely independent entrance and exit fracture patterns.

Models using defect dimensions performed well internally (100% accuracy) and across observers (Model 1: 97.5-100%; Model 3: 87.5-100%) but declined in the external dataset (Model 1: 85.0%, Model 3: 86.7%). Misclassifications were caliber-dependent: small caliber exits (.308) and large caliber entrances (.40) were often misclassified, with Model 3 showing significant bias ($p = 0.039$). Maximum, minimum, and ratio of diameters were top predictors in both models. Model 2 (fracture counts and lengths only) achieved 95.83% internal accuracy but was less accurate across observers (74.2%-79.5%) and externally (60%). Adding defect ratio (Model 4) did not improve accuracy (internal: 91.67%; interobserver: 82.1–82.5%; external: 66.67%). Neither model showed caliber bias. Radial crack count, minimum radial crack length, and total fracture length were among the top predictors, though defect ratio dominated Model 4. Combining n=60 and n=30 datasets to train on multiple calibers did not substantially improve accuracy or change variable importance.

Discussion: This study revealed side-specific differences in projectile defects, clarifying variables that could support side prediction. However, when incorporated in models, performance declined across calibers and inter-observer variation reduced accuracy. Defect dimensions were consistently ranked top predictors, reflecting the known tendency for entrances to be smaller than exits, but variability by caliber limits broader forensic applicability. As a case study, this work underscores challenges in applying ML to trauma analysis, including training set specificity, category overlap, and observer effects. While ML can identify and prioritize predictive variables, basic analyses of fracture features reveal interpretable differences that clarify why models succeed or fail under diverse conditions.

A143 Primary Skeletal Blast Trauma: Examining the Effects of the Blast Wave on Skeletal Trauma Using Postmortem Human Subjects and Non-Human Proxies

Petra Banks, PhD, University of Alaska Fairbanks, Fairbanks, AK*

Learning Objectives: Attendees will learn the results of experimental blast events conducted at the Forensic Anthropology Center at Texas State using four postmortem human subjects and two non-human proxies. The minimal fractures resulting from these blasts indicate that secondary blast trauma may be causing more of the fractures observed in non-experimental settings than previously understood. Additionally, fracture patterns attributed to primary blast wave impacts in previous publications using non-human proxies were consistent with what was observed in these experiments.

Impact Statement: The results of this study indicate that there is still much to learn regarding the mechanisms of skeletal trauma in blast events. Some fractures observed reflected previously published research on primary blast trauma, but other results indicate that what is commonly believed to be primary blast trauma (caused by the blast wave) may be caused by secondary blast trauma (shrapnel or fragmentation). This knowledge may assist forensic anthropologists and investigators in a more comprehensive understanding of the mechanisms of injury in blast event cases.

Abstract Text: Skeletal blast trauma has mostly been researched and understood through case studies and experimental research using non-human proxies. Case studies, although representative of the type of work forensic anthropologists, pathologists, and investigators may encounter, are not ideal as a research source because they are not controlled or replicable, and data between cases can vary widely. Non-human proxies, while providing a useful method for examining preliminary fracture patterns, are different in both structure and composition from humans and often are positioned in unnatural positions for their anatomy (e.g., quadrupeds positioned to simulate bipedal orientation). To explore this gap in research, experimental blasts were conducted at the Forensic Anthropology Center at Texas State University using four postmortem human subjects, donors to the Willed Body Donation Program who had indicated their willingness to be used in traumatic research prior to death. In addition, six non-human proxies (*Sus scrofa*) were subjected to blasts; four used to test the viability of the blast structure and appropriate distances prior to the donor tests, two placed in the exact same circumstances as the donors to provide non-human proxy comparative data. The initial four non-human proxy blasts took place at White Sands Missile Range in New Mexico with the assistance of the 741st EOD of Fort Bliss.

The subjects were all attached to a structure that simulated a person standing upright. The structure and attachments were designed to allow the subject to fall back naturally when impacted by the blast, thereby reducing the likelihood of trauma due to the structure attachments. The blasts impacted two donors and one non-human proxy anteriorly, and two donors and one non-human proxy laterally. C4 was used for the explosive and was handled and managed by the San Antonio Police Department Bomb Squad.

Data collection included initial body composition measurements, including weight, height, and limb and waist circumferences, as well as Computed Tomography (CT) scans of the four donors and two of the non-human proxies both before and after the blast events at the Office of the Medical Examiner in Albuquerque, NM. Additionally, high-speed cameras recorded the blasts from two angles, and total station points and 3D scans were taken of the scenes before and after the blasts. Finally, in addition to analyzing the CT scans for fractures, the donors and proxies were placed out at the decomposition facility for a year to decompose, and then the bone was processed for physical fracture analysis.

The experimental blast trauma results indicate that, unlike previous publications on primary blast trauma, there are minimal fractures caused by the full body blast wave impact without fragmentation or shrapnel present, indicating that the high rates of fractures in blast events may be mostly caused by secondary blast trauma. The fractures observed from the primary blast wave were focused in the ribs, sternae, and vertebrae, with additional facial fractures. Rib fractures consistent with other experimental blast research using non-human proxies were observed.[1] However, unlike reports in previous publications, the blast wave did not cause any traumatic limb amputations.[2-4]

A144 Evaluating Dimensional Changes in Long Bones Exposed to Fire

Joe Adserias-Garriga, PhD, Mercyhurst University, Erie, PA; Laia Nogue, MS, Universitat de Vic, Vic, Catalonia, Spain; Luis L. Cabo, MS, Mercyhurst University, Erie, Pennsylvania; Marta Fernandez-Viejo, MS, Universidad de Burgos, Burgos, Castilla y Leon, Spain; Laura Rodriguez, PhD, Universidad de León, León, Castilla y Leon, Spain; Rebecca Garcia-Gonzalez, PhD, Universidad de Burgos, Burgos, Castilla y Leon, Spain*

Learning Objectives: Attendees of this presentation will acquire a better understanding of how shrinkage and warping behaves when long bones are exposed to fire under controlled high-temperature conditions.

Impact Statement: This presentation will impact the forensic science community by providing innovative information on the dimensional alterations of long bones exposed to fire, enhancing interpretation accuracy in identification and trauma analysis.

Abstract Text: Shrinkage and warping of human bones exposed to fire significantly impact forensic investigations, especially in contexts involving identification and trauma interpretation. Previous studies have documented alterations to skeletal remains caused by high-temperature exposure, recognizing shrinkage and warping as critical elements influencing the reliability of osteological analyses.[1-3] However, inconsistencies remain in quantifying these effects in skeletal elements, limiting the interpretative accuracy in forensic anthropology.[4] Previous studies have validated Computed Tomography (CT) imaging as an accurate method for assessing dimensional bone changes, allowing the visualization of subtle morphological alterations not easily detected by conventional means.[5,6]

The goal of the present study is to evaluate shrinkage and warping in long bones, specifically the humerus, through controlled exposure to fire. Sixty-six human humeri consisting of 33 pairs (left and right elements from the same individual) were subjected to high-temperature conditions within a commercial cremation retort until calcination was achieved. Each humerus was scanned using CT before and after cremation, providing accurate measurements for their evaluation and comparison.

The CT scans were analyzed using the 3D Slicer software. To segment the different bones, the "Grow from Seeds" tool within the Segment Editor module was employed to distinguish between various tissues. In cases where the skeletal remains were fragmented, each fragment was individually segmented and subsequently merged to create a unified segmentation. This process also utilized the "Grow from Seeds" method. Upon completion of the segmentation, the "Segment Statistics" module was used for quantification. The variables measured included voxel count and volume, expressed in both mm^3 and cm^3.

Our results demonstrate measurable shrinkage and warping in humeri post-cremation, to bone mineral density, cortical thickness, and initial bone size. Additionally, warping patterns were identified, which are consistent with the anisotropic nature of bone and its biomechanical properties under thermal exposure. The application of CT scans proved instrumental in detecting nuanced dimensional changes and providing quantifiable data regarding bone deformation due to fire exposure.

This study contributes with critical insights into the predictable yet complex responses of human bones to fire exposure. Future research should expand the scope to include comparative analyses of other bones and assess the influence of demographic variables, such as age and sex, to further refine interpretive frameworks applied to burnt skeletal remains.

A145 A Preliminary Comparative Assessment of Digital Imaging Modalities for Fractographic Analysis

Delaney Edwards, MA, The Ohio State University, Columbus, OH; Angela L. Harden, PhD, Injury Biomechanics Research Center, Columbus, OH; Mary E. Cole, PhD, The Ohio State University, Columbus, OH*

Learning Objectives: Attendees will gain an increased understanding of how different imaging modalities capture fractographic features and how these modalities compare to each other and traditional visual analysis.

Impact Statement: This presentation will impact the forensic science community by providing a wide-scale comparison of imaging modalities for fracture surface analysis, assessing whether visual assessment-based definitions are valid across methods such as micro-Computed Tomography (micro-CT) and 3D surface scanning.

Abstract Text: Forensic fractography, the visual assessment of fracture surfaces, is increasingly used to identify features linked to fracture initiation and propagation, aiding in trauma reconstruction.[1] As its application to bone evolves, digitizing fracture surfaces offers benefits for peer review in casework, training, and data sharing for research. To effectively integrate digital tools into the workflow of forensic fractography, it is essential to evaluate how various digital imaging modalities perform relative to one another and traditional visual methods. This research aims to assess their comparative ability to visualize fractographic surface features using established definitions.

Fractographic analysis was conducted on ten human tibiae (75.9 ± 14.4 years; three males, seven females) previously impacted in controlled, dynamic 4-point bending tests. Each discrete fracture surface (n=32) was examined using five modalities: gross visual examination, photogrammetry (Agisoft Photoscan Professional), laser scanning (Quantum FaroArm), Vereos clinical CT, and 3D optical profilometry (Keyence VR-6000 series). Vereos clinical CT scans were acquired post-experiment and reconstructed for surface analysis. All specimens were macerated and dried, and fingerprint powder was applied to all fracture surfaces prior to visual, photogrammetric, laser, or profilometer data collections. Each fracture surface was assessed using each imaging modality, assessing the presence or absence of bone mirror, hackle, arrest ridges, wake features, and cantilever curl in accordance with current standards for visual examination.[1]

Every imaging modality facilitated the identification of every fractographic surface feature, but with varying rates of occurrence. Bone mirror was most frequently observed in photogrammetry (81%; other methods 50%–66%); hackle in optical profilometry (97%; other methods 63–88%), and arrest ridges in CT models (94%; other methods 63–81%). Cantilever Curl appeared most often in gross visual and CT analysis (94%; other methods 72%–91%) while wake features were primarily identified through visual analysis and CT (34%; other methods 9–12%).

Findings support the development of standardized, modality-appropriate protocols to improve consistency and reliability in forensic skeletal trauma interpretation. Digital imaging modalities that involve scanning along or through the bone surface (e.g., laser scanning, CT, profilometry) more frequently captured smaller features, such as hackle, but less frequently identified the “relatively featureless area” characteristic of bone mirror. This may be due to the higher resolution of these modalities revealing a more textured surface. In contrast, photogrammetry exceeded even visual examination in bone mirror frequencies, potentially because it triangulates points visible from multiple camera angles, which may have a smoothing effect on surface texture. These preliminary results suggest that the definitions of fracture surface features should be tailored to specific imaging modalities to increase their accuracy and consistency. Future work will expand the sample size and refine definitions of fractographic features for these digital techniques.

A146 A Comparison of Postmortem Radiograph Modalities for the Detection of Infant Skeletal Trauma

Miriam E. Soto Martinez, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Jason M. Wiersema, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Julie M. Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Si Gao, MS, Harris County Institute of Forensic Sciences, Houston, TX; Michal Pierce, MS, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: After attending this presentation, attendees will understand the accuracy and reliability of different imaging modalities used by forensic anthropologists at the Harris County Institute of Forensic Sciences (HCIFS) to identify infant skeletal trauma.

Impact Statement: Gross detection of infant skeletal injuries, particularly metaphyseal fractures using the Pediatric Skeletal Exam (PSE) protocol is an effective but destructive and inefficient process.[1] This presentation will impact the forensic science community by systematically evaluating radiographic alternatives to the PSE. The ability to use imaging modalities has the potential to reduce the invasiveness of anthropological trauma examinations of infants by enhancing the ability to better visualize subtle injuries without soft tissue destruction.

Abstract Text: HCIFS anthropologists evaluated three imaging modalities on a sample of 20 infants (< 12 months old) autopsied at the HCIFS. Each case received full body imaging via postmortem computed tomography (PMCT), a low dose radiographic scan (LODOX), and high-resolution Digital Radiography (DR) skeletal survey. The PMCT and LODOX imaging were performed pre-autopsy. The Forensic Anthropology Division (FAD) staff performed the DR imaging and conducted *in situ* rib examinations of each case post-autopsy. After reviewing the DR imaging, the FAD staff, per autopsy protocol, resected, processed, and examined grossly and microscopically skeletal elements with suspected trauma to confirm the presence of fractures. The grossly observed skeletal trauma represented the "known" injury data and was used for comparison with the imaging modality data.

Presence/absence of fractures for 93 specified bones/bone regions was recorded. FAD anthropologists individually evaluated the imaging for each case, beginning with LODOX, followed by DR and PMCT. After all imaging was reviewed by the observers, the "known" injury data was coded for comparison with the imaging data.

Reliability and accuracy were evaluated using univariate and non-parametric statistical tests. Cohen's Kappa statistics were calculated for all combinations of observers for each modality to evaluate inter-rater agreement. Contingency tables and chi-square test were used to calculate accuracies and test for significant differences between the "known" and imaging data. McNemar statistics tested for significant differences between imaging modalities for correctly/incorrectly identifying fractures of specific bones.

There was significant ($p < .05$) inter-rater agreement between all observers for all modalities. Agreement using the DR imaging ranged between substantial and almost perfect ($\kappa = .646 - .806$). For the PMCT imaging, agreement ranged between moderate and almost perfect ($\kappa = .427 - .881$). The agreement for the LODOX imaging was the lowest, ranging from moderate to substantial ($\kappa = .524 - .619$).

A chi-square test indicates no significant difference between the "known" and PMCT data ($p = .21$). There are significant differences between the "known" and DR ($p = .001$) and LODOX ($p < .001$) data. The McNemar tests indicate no statistically significant relationship between the ability to correctly identify fractures of specific bones/regions based on modality. Accuracies for identifying fractures were high for all modalities, but was highest for PMCT (97.2%), followed by DR (94.9%), and LODOX (94.3%).

The results indicate that FAD staff were able to reliably and accurately identify skeletal trauma in infants regardless of the imaging modality utilized. The highest accuracy for identifying skeletal trauma was achieved using modalities with the highest resolution: PMCT and DR. Subjectively, FAD anthropologists agree that collimated DR images more clearly depict the metaphysis and metaphyseal injuries than does full body PMCT, but there is insufficient metaphyseal fracture data in the current study to quantify that assertion. However, PMCT is subjectively and statistically better for detecting rib fractures than either other imaging modality.

A147 A Micro-CT Analysis of False Start Marks on Fire-Exposed Human Bones

Laura Secco, MD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Ludovico Fava, MD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Chiara Giraudo, MD, PhD, University of Padova, Padova, Veneto, Italy; Guido Viel, MD, PhD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Stefano Palumbi, MD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Giovanni Cecchetto, MD, PhD, University of Pavia, Department of Public Health, Experimental and Forensic Medicine, Padova, Veneto, Italy*

Learning Objectives: After attending this presentation attendees will learn how micro-Computed Tomography (micro-CT) can be applied to analyze false start marks on human bones before and after fire exposure. The presentation will demonstrate that heat-induced changes do not significantly affect morphological and morphometric parameters relevant for tool identification. Participants will gain insights into the implications of fire exposure on the preservation and detectability of toolmarks and will learn how to perform a detailed morphometric analysis of false start marks to accurately identify the type of tool used.

This session will provide evidence supporting the robustness and reliability of micro-CT for forensic toolmark analysis, even in burned skeletal remains, with direct relevance to forensic casework involving body concealment through dismemberment and burning.

Impact Statement: This presentation will enhance the forensic science community's ability to reliably identify and assess saw marks on fire-exposed human bones using micro-CT imaging. By demonstrating that key morphological and morphometric features of false start marks remain stable after fire exposure, the study supports accurate and confident toolmark interpretation in fire-related forensic contexts. These findings can improve the performance of forensic pathologists during postmortem examinations of burned skeletal remains, contributing to more accurate reconstructions of perimortem events involving body concealment through dismemberment and burning, with clear implications for medicolegal investigations and judicial proceedings.

Abstract Text: Recently, micro-CT has been successfully applied for the morphological and morphometric analysis of false start marks on bone samples, aiding in the identification of the tool used for their production.[1,2] It is well established that heat alters bone tissue, affecting its color, weight, volume, shape, fracture patterns and histological features.[3] Although previous research has shown that bone lesions may remain identifiable after fire exposure, heat-induced changes are still largely unknown and require further investigation.[4] This study aims to investigate the role of micro-CT in the identification and characterization of saw marks on human bones before and after fire exposure, in order to assess whether heat-induced changes affect false start marks.

Two distinct false start marks were produced on 30 bone samples obtained from human fibulae using a crosscut and a rip-cut saw. Marks were manually inflicted by sliding the saw blades perpendicular to the long axis of the bones. The bone samples were divided into two groups and exposed to direct flame from a camping burner stove for 3, 9, and 15 minutes (Group 1) and 6, 12, and 18 minutes (Group 2), respectively, at temperatures ranging between 600°C and 800°C.

All samples were photographed and scanned using high-resolution Micro-CT before and after each burning interval. The acquired raw data were reconstructed using N-Recon Software, converted in Digital Imaging and Communications in Medicine (DICOM) format using DICOM Converter Software, and analyzed with Horos software for multiplanar and 3D volumetric reconstructions.

A preliminary qualitative morphological evaluation and a subsequent morphometric assessment were manually performed on the sagittal plane, measuring the following parameters: top kerf width, depth, bottom kerf width, and angles degrees. Such features were thus compared across burning intervals to assess potential differences in false start marks produced by the same saw before and after each fire exposure.

Up to the maximum burning time tested, false start marks remained macroscopically visible after each fire exposure. Micro-CT analysis enabled detection and detailed morphological characterization of false start marks on both fresh and burned bone specimens. No significant alterations in the morphology (i.e., kerf angles, floor, central bone island) or size of the false starts were observed after each burning cycle, thus allowing for the identification of the type of saw used in all cases.

Our preliminary findings suggest that fire exposure does not obscure false start evidence on bone surfaces nor compromise their micro-radiological evaluation. Micro-CT appears to be a reliable technique for both qualitative and quantitative analysis of false start marks, even in charred human bones, providing valuable information for tool identification. Although these results are promising, further research is required to assess the effects of varying temperatures and fire exposure durations before definitive conclusions can be drawn.

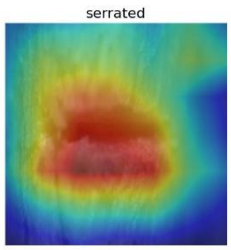
A148 Opening the Black Box: Visualizing AI Decisions in Forensic Trauma Analysis

Giada S. Steiger, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will gain insight into how post-hoc Explainable Artificial Intelligence (XAI) methods, such as Gradient-weighted Class Activation Mapping (Grad-CAM) and Local Interpretable Model-Agnostic Explanations (LIME), can be applied to interpret and evaluate deep learning models specifically for cut mark classification. Additionally, they will recognize the practical significance of integrating explainability to ensure trustworthy, transparent, and robust forensic analysis.



Impact Statement: This presentation will impact the forensic science community by demonstrating how integrating XAI methods into forensic anthropology can enhance transparency and trust in automated decision-making while upholding ethical standards and scientific rigor. By revealing how deep learning models generate classifications, these approaches help ensure that forensic evidence remains robust, interpretable, and reliable.

Abstract Text: Forensic anthropology is advancing rapidly through the integration of AI, making it essential to uphold the discipline's ethical standards and scientific rigor to ensure these powerful tools enhance analysis and improve accuracy without compromising justice.

The 2019 *Ethics Guidelines for Trustworthy AI* established key values such as human oversight, transparency, and fairness, which have since been codified in the EU AI Act.[1,2] This legislative shift transforms ethical ideals into enforceable rules to ensure the safe and trustworthy use of AI across Europe. Within this framework, the use of AI in law enforcement and in assisting with the interpretation and application of the law is considered high risk because of its potential impact on public safety and on the protection of fundamental rights. The application of machine learning models in these sensitive domains raises significant concerns. While simpler machine learning models may offer a degree of interpretability, deep learning models are often criticized as "black box models" due to their complex and opaque decision-making processes, which limit both transparency and trustworthiness. In judicial and forensic contexts, it is essential to identify and mitigate potential sources of bias that could influence decision-making.[3] A lack of a clear explanation of how these models reach their conclusions could undermine the confidence and fairness demanded by legal stakeholders.

Recent developments in XAI have highlighted the potential of this approach to clarify model predictions. XAI methods can be broadly categorized as either model-based, where interpretability is incorporated during model design, or post-hoc, which provide explanations for predictions after model training.

This study aims to explore the application of two XAI methods to assess whether deep learning classifiers are utilizing appropriate features for cut mark classification. Based on the exploratory work of Nikolić et al., Class Activation Mapping (CAM) and Local Interpretable Model-Agnostic Explanations (LIME) were implemented on the predictions of previously trained models.[4,5] The models were trained to classify knife-inflicted cut marks into serrated versus non-serrated and single- versus double-beveled categories. CAM and LIME were applied to visualize decision-making and identify sources of misclassification. The results of these techniques can be visualized as overlays that highlight the regions of the image the model focuses on (Figure 1).

The visualization revealed that although the models achieved correct classifications, attention was sometimes directed toward background areas rather than diagnostic features.

These findings underscore that performance metrics alone are insufficient to guarantee forensic reliability. Performance metrics, while essential, do not capture whether models base their decisions on valid features. Without explainability, models risk relying on spurious correlations or background noise, leading to unreliable or unethical decisions. Therefore, this study offers insight into the integration of XAI techniques that can ensure deep learning-driven decisions are ethical, evidence-based, and robust for forensic practice.

A149 Harnessing Machine Learning to Evaluate Microscopic Characteristics of Skeletal Trauma

Keivan Nalaie, PhD, Mayo Clinic, Scottsdale, AZ; Jessica Skinner, PhD, University of Chicago, Twin Lakes, WI; Aurely Sanchez Carreon, BS, Mayo Clinic, Buckeye, AZ; Loukham Shyamsunder, PhD, Indian Institute of Technology Tirupati, Tirupati, Andhra Pradesh, India; Subramaniam Rajan, PhD, Arizona State University, Tempe, AZ; Natalie Langley, PhD*, Mayo Clinic, Scottsdale, AZ*

Learning Objectives: After attending this presentation, attendees will be able to describe how and why microscopic fracture surface features change throughout the postmortem interval. They will also be able to discuss the value of machine learning algorithms for analyzing Scanning Electron Microscope (SEM) images of bone fracture surfaces and mitigating observer bias in data collection and case analyses. Attendees will attain foundational knowledge about automated systems that bolster practitioner analyses and offer a means for standardizing fracture timing assessment procedures while maintaining the scientific rigor required for forensic evidence.

Impact Statement: This presentation will impact the forensic science community by demonstrating machine learning models' utility in solving common forensic dilemma: assessing fracture timing. Practitioner competence will be enhanced by tools that automate and integrate complex data analysis, improving accuracy in distinguishing peri- and postmortem bone defects beyond traditional methods. Our goal is to boost performance by enabling faster, more reproducible assessments that reduce manual errors and processing time, allowing practitioners to apply these models to forensic casework for precise predictions.

Abstract Text: Microscopic fracture surface features are more predictive than macroscopic fracture patterns for distinguishing perimortem trauma from postmortem damage.[1] This study investigates the utility of a multi-modal machine learning framework leveraging SEM images of fracture surfaces and tissue integrity assessments to predict fracture timing.

Experimental fractures were induced in 37 defleshed human femoral shafts using a drop test frame with three-point bending and a 100–275mm drop height. Eight femora were used as the perimortem sample, and 29 femora were heated in a gravity convection oven to simulate postmortem intervals between 1,000–40,000 Accumulated Degree Hours (ADH). Tissue integrity assessments included water loss, collagen percentage, cortical thickness, Bone Mineral Density (BMD), and fracture energy parameters.

A three-pronged approach was employed to compare the computer vision analysis based on 981 SEM fracture surface images to our previous results from observer-defined Regions Of Interest (ROI) in 74 SEM images (two rounds of assessment on blinded image ROIs) of the same fracture surfaces.[1] The first modeling strategy used the tissue integrity variables to predict ADH at the time of fracture. This approach hypothesized that bone undergoes predictable, quantifiable biochemical and biomechanical changes during decomposition. The second approach utilized deep learning algorithms trained on visual characteristics of SEM images of bone fracture surfaces (magnification=30X). The deep learning model automatically identified microscopic features indicative of bone elasticity at the time of fracture and detected morphological changes in fracture surface topography that may be imperceptible to human observers. The third approach integrated the tissue integrity variables and computer vision analysis into a predictive model. This hybrid methodology combined the quantitative precision of biochemical measurements with the pattern recognition capabilities of deep learning to create a robust framework for determining fracture timing.

The LargeMobileNet architecture from the PyTorch library was used to train the image-based model, and a Support Vector Machine (from the Scikit-learn library) was used to integrate SEM image features with tissue integrity variables. The models were trained to distinguish between three ADH categories: perimortem (ADH=0, n=118), early postmortem (ADH=1000-3000, n=255), and late postmortem (ADH=6000-40,000, n=608); each experiment was repeated eight times. The following summarizes the mean accuracy of the methods: using only tissue integrity variables yielded an accuracy of 65.7%; the accuracy from relying solely on SEM fracture surface features extracted via the deep learning model was 59.5%; combining tissue variables and deep learning-derived image features increased accuracy to 76.6%. This result is comparable to the practitioner-derived results (70%-78% accuracy) based on osteon pullout, delamination, and microfractures.[1]

The deep learning methodology's strength lies in its comprehensive evaluation of bone degradation processes and microscopic structural changes occurring along predictable timelines that can be leveraged for forensic applications. Additionally, the study's controlled experimental conditions mean the results are highly reproducible. We are working to fill ADH data gaps to construct a deep learning model with greater predictive power and mitigate model bias related to sample distribution. Future areas of innovation for this work include micro-Computed Tomography (micro-CT) surface complexity analysis and three-dimensional computer vision analyses.

A150 Developing Evidence-Based Approaches for Taphonomic Histories: A Call for Communication Across the Disciplinary Divide

Derek A. Boyd, PhD, University of Nevada, Las Vegas, Las Vegas, NV; Angela M. Dautartas, PhD, Western Carolina University, Waynesville, NC; Hayden S. McKee-Zech, PhD, Northern Michigan University, Marquette, MI; Erin A. Patrick, MSc, University of Tennessee Knoxville, Knoxville, TN; Kelly Sauerwein, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: This presentation will highlight the need for continued interdisciplinary efforts in forensic taphonomy and Postmortem interval (PMI) estimation research, including the benefits, limitations, and applications associated with such collaborative efforts.

Impact Statement: This presentation will help promote a better appreciation for interdisciplinary collaboration and the evaluation of the reliability, capabilities, and limitations of forensic taphonomic methods and practices across multiple forensic disciplines.

Abstract Text: PMI estimation is complicated by myriad biological, ecological, and geological factors that influence the rate of human decomposition. In the past decade, forensic science has seen an influx of analytical techniques and statistical methods, including machine learning algorithms, bioinformatics, and systems biology approaches, that have the potential to elucidate ecological interactions in decomposition that could revolutionize PMI estimation.[1-3] While this cross-discipline approach has become a hallmark of forensic taphonomic and PMI estimation research, the field continues to face two major challenges. The first challenge is the siloing of information within forensic disciplines, which impacts innovation and the implementation of new tools. This is evidenced by the 2025 AAFS Annual Meeting where 37 talks on human decomposition were spread across four different section-specific sessions: 16 in Anthropology, 5 in Criminalistics, 6 in General, and 10 in Pathology/Biology.[4]

Keeping conversations about human decomposition structurally siloed creates obstacles to leveraging the strengths and limitations of different disciplines in the development of interdisciplinary PMI methods. The second challenge concerns the fact that more research is needed to understand the dynamic, chaotic, and non-linear nature of decomposition before PMI estimation methods can truly reap the benefits of interdisciplinary collaborations. While this exploratory work may itself benefit from interdisciplinarity, the strengths, limitations, and future trajectories of taphonomic research within specific disciplines are best understood by the subject matter experts in those disciplines. Communication without collaboration risks misapplying core scientific principles and overlooking discipline-specific limitations that may be compounded in interdisciplinary PMI methods, impairing accuracy, reliability, and validity. The focus of this presentation is to synthesize and facilitate discussion surrounding the current challenges facing research, development, implementation, and training in interdisciplinary taphonomic methods.

Given these challenges, we advocate for a unified interdisciplinary infrastructure to provide informational resources for approaching human decomposition research and navigating PMI methods in routine casework. This coalition will bring together experts from across the forensic sciences to evaluate the state of forensic taphonomy, to identify critical information gaps, and to set recommended priorities for future research that capitalizes on analytical and technological advances in Science, Technology, Engineering, and Math (STEM). A future project to build this infrastructure will develop an online platform for disseminating information about discipline-specific principles, methods, workflows, and limitations to a wide audience of practitioners, researchers, scientific experts, legal professionals, educators, and other interested stakeholders. We encourage members of the forensic science community to recognize and discuss these challenges as they work to better understand human decomposition and to make concomitant improvements to PMI estimation that yield greater accuracy, precision, and replicability.

A151 A Foundational Exploration of the Scavenger Guild in Baltimore, Maryland

Marion Davidson, MSc, University College London, Baltimore, MD*

Learning Objectives: After attending this presentation, attendees will have an improved understanding of the small scavengers present in Baltimore, MD, and how they interact with remains during the summer months.

Impact Statement: This presentation will impact the forensic science community by presenting the findings of a pilot study identifying the local scavengers in the Baltimore area, highlighting the need for location-specific research and data collection.

Abstract Text: Estimating the postmortem interval remains one of the most important, albeit difficult, aspects of forensic science.[1] This is complicated by animal scavenging, which has the potential to impact decomposition and, in turn, affect the estimation of time since death. Literature in forensic taphonomy has highlighted gaps in basic research, particularly a lack of studies that explore taphonomic alterations across a range of environments.[2] Moreover, practitioners have acknowledged that an understanding of local scavengers can assist in the interpretation of damage on skeletal remains in casework.[3] Therefore, the aim of this pilot study was to identify the animal scavengers active in the city of Baltimore, MD, in an effort to directly assist the local authorities in their medicolegal death investigations.

Following Pokines and Pollock, data was collected on Loyola University Maryland, in an unfenced, wooded area that spans approximately 25 acres.[4] The majority of the land is densely covered with mature trees that provide a decent canopy layer. This land is surrounded by a walking trail, a highway, a college sports field, and a residential neighborhood. Four wire cages (60cm by 45cm by 48cm) were placed at least 30 meters apart in areas of varying tree coverage and vegetation density. Each site was monitored by a motion-sensitive, infrared trail camera that was attached to a wooden stake placed in the ground within one meter of the cage. Commercially obtained, fresh but mostly defleshed pig (*Sus scrofa*) femora were zip tied to bottom of each cage. In an effort to increase animal interaction, three of the four cages additionally received an ethically sourced raccoon carcass. The initial femora were placed in the beginning of June 2025 and subsequently replaced approximately once a week for just under two months (n=28).

Preliminary results indicate that the most common interactions involved foxes (*Vulpes vulpes*), followed by opossums (*Didelphis virginiana*) and raccoons (*Procyon lotor*), with most animal involvement occurring between 9:00 pm and 2:00 am. Analysis revealed that foxes not only spent the most amount of time interreacting with the bones—sometimes more than three consecutive hours—but were also observed removing several of the bones entirely, resulting in the permanent loss of three specimens. Additional animals were identified, such as deer (*Odocoileus virginianus*) and groundhogs (*Marmota monax*); however, these were likely incidental faunal traffic. Continued analysis will involve the removal of the remaining soft tissue as well as the identification of the taphonomic damage and the probable associated animal.

This pilot study provides empirical documentation of the scavengers active in Baltimore, MD, during the summer months, offering location-specific data that can strengthen medicolegal death investigations. The results show that this scavenger guild is primarily nocturnal, with foxes playing a dominant role and capable of removing bones entirely. This research underscores the importance of understanding how scavengers interact with remains in terrestrial environments. Although preliminary, these findings supply fundamental data that can assist in the interpretation of animal scavenging in Maryland, which is valuable to the estimation of the postmortem interval and forensic investigations.

A152 The Detection of Decomposition in Soil With Portable X-Ray Fluorescence

Rhys Williams, PhD, Loyola University Maryland, Baltimore, MD*

Learning Objectives: This presentation explores the applicability of portable X-Ray Fluorescence (pXRF) for identifying the elemental composition of blood and decomposition fluid leaching into soil. Attendees will learn which elements and at what accumulation may indicate the location of the body. The method and interpretations provided may be incorporated with scene search strategies for locating deposition sites or sites of aggression.

Impact Statement: In situations where the location of buried remains is contested, the investigation team may be limited to few techniques, methods, time, and financial support. This paper explores pXRF as a portable and non-destructive method in detecting elemental accumulations in soil following decomposition or deposition. Investigation teams seeking to expand their grave location toolset may benefit greatly from the inclusion of pXRF soil surveying, with systematically validated protocols provided in the presentation being suitable for soil across any environment.

Abstract Text: The location of buried remains is a key part of many missing persons cases. There is a necessity for rapid and low-cost techniques to delimit the search area or corroborate with locations flagged for excavation, particularly when alternative techniques are unavailable or unsuccessful. However, soil analysis is often omitted when examining burials despite composing the grave itself. pXRF is a rapid and non-destructive technique with systematically developed protocols for examining elemental content of soils.[1] Elemental analysis has previously been used in archaeological applications such as delimiting the boundaries of locating cemeteries or for interpreting settlements and waste areas from historic communities.[2,3] This project explores the applicability of pXRF for examining the change in elemental composition of soil following decomposition through early timescales.

Initial investigations added increasing seriations of blood into compost soil (0, 10, 20, 30% by weight), homogenized blood and soil together, and held prepared samples in sealed containers for analysis at set intervals (1 day, and 1, 2, and 3 weeks). Alongside the controled blood serialization study, pigs (*Sus scrofa*) were laid inside vinyl-coated open-bottomed cages for outdoor surface decomposition with seasonal sampling of the soils beneath the bodies for one year. Soils were oven-dried, homogenized, and examined with pXRF using fundamental parameters. Soils showed statistically significant increases in Al, P, S, K, Ca, and Fe compared against control and pre-deposition soil samples, reflecting the addition of components of blood, body fluids and bone. Furthermore, elemental increases persisted across serialized concentrations and the experiment length, demonstrating the elemental persistence when detecting decomposition in soil.

A153 Taphonomic Analyses of Hair: From Postmortem Root Banding to Environmental Degradation

Sandra Koch, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: The goal of this presentation is to share in an interdisciplinary setting the taphonomic alterations hair can undergo (e.g., postmortem root banding, fungal tunneling) and under what conditions. This presentation will also discuss how microscopical examination of hairs can provide valuable investigative information and inform research efforts on the postmortem interval.

Impact Statement: This study will impact the forensic community by providing guidance on what postmortem root banding looks like at various stages. Learning the stages of decomposition that hairs can undergo and what can legitimately be stated versus what qualifying factors should be acknowledged will lead to a greater understanding of environmental degradation versus decomposition.

Abstract Text: Hair can often be found in forensic contexts, and the analysis of this evidence can provide valuable information regarding potential sources (i.e., whether it is from a human or animal). Morphological alterations to hair structures can be related to the environmental conditions or events under investigation so a thorough awareness of hair microstructure, its relative stability, and how it may differ across populations, from diseases, or from external forces is critical to its application in forensic research and casework. Cross-disciplinary understanding of the variability in mammalian hair microstructure and how hairs can degrade under different environmental conditions or from the decomposition process is important for a range of studies, including the Postmortem Interval (PMI). Microscopical examinations of hair can provide confirmatory information about hair treatment or alteration and aid studies of postmortem alteration if the different causes of degradation are understood outside of discipline-specific silos. Familiarity with the potential taphonomic alterations that can occur in hair evidence can be informative in the decision process on whether or not to pursue other forensic analyses. While hairs are typically a stable material, the decomposition process and environmental conditions can impact whether DNA can be obtained from the root or hair shaft. The geographic location, surface or burial placement, and duration of exposure that bodies undergo during decomposition can alter the microstructure of hairs and potentially their isotopic ratios. This presentation will review the stages of decomposition-related alteration in hairs, including the presence of a postmortem root band, insect and environmental damage not specifically related to decomposition, and other alterations to hair morphology and microstructure.[1-17]

A154 Application of geoFOR at the Anthropology Research Facility (ARF)

Tempest D. Mellendorf, MS, University of Tennessee, Knoxville, Knoxville, TN; Devin L. Adcox, MA, University of Tennessee Knoxville, Knoxville, TN; Sydney Munkus, BS, University of Tennessee Knoxville, Knoxville, TN; Victoria Eacott, BA, University of Tennessee, Knoxville, Knoxville, TN*

Learning Objectives: Attendees will learn how GeoFOR functions as a predictive tool for estimating Postmortem Interval (PMI) using decomposition and insect and vertebrate activity data along with geospatial modeling. They will be able to assess the tool's predictive accuracy based on validation results from outdoor human decomposition cases at the Anthropological Research Facility. By the end of the presentation, attendees will be able to critically evaluate the strengths and limitations of GeoFOR in forensic applications and identify key factors that influence model performance in field settings.

Impact Statement: This presentation will inform forensic practitioners about the current capabilities and limitations of GeoFOR, a novel machine learning-based tool for PMI estimation, enhancing their competence in evaluating emerging technologies in forensic taphonomy. By demonstrating the tool's variable performance in outdoor conditions, it encourages critical assessment and refinement of predictive models, ultimately supporting the development of more reliable methods that can improve casework accuracy and consistency across forensic investigations.

Abstract Text: Human decomposition is a complex process due to the extensive intrinsic and extrinsic variables that affect its rate. Due to this complexity and lack of consistency amongst forensic practitioners, providing an accurate postmortem interval (PMI) has proven difficult. However, in 2024 geoFOR, an online based tool that combines machine learning and ArcGIS was created to provide users with a PMI prediction.[1] This model was generated based on 2,529 entries collected from a collaborative forensic taphonomy database.[2] The purpose of creating geoFOR was to produce a more robust and standardized methodology of predicting the postmortem interval of decedents based on decomposition, insect, and vertebrate characteristics. geoFOR's accuracy was evaluated using data from human donors placed on the surface at the Anthropology Research Facility in Knoxville, Tennessee. The study included observations from individuals with known dates of death, allowing for a direct comparison between actual and predicted postmortem intervals. Over the course of the study period, a total of 102 decomposition observations were submitted to the geoFOR application. Predictions were classified as either "in range" or "out of range" based on whether the known postmortem interval fell within the tool's predicted date range. An exact binomial test revealed that the observed proportion of successes ($k = 52$, $N = 120$) or "in range" observations was significantly different (p-value < 0.00; 95% CI: 0.41-0.61) from the expected proportion of .80. This suggests that the reported 80% success rate is unlikely to be accurate and is more plausibly within the range of approximately 41% to 61% indicating limited accuracy in this outdoor context. For donors with multiple observations, average prediction accuracy was 61%, suggesting potential but inconsistent performance over time. These findings highlight the need for further refinement of geoFOR's predictive capabilities, particularly when applied to specific environments such as surface deposition in outdoor forensic settings.

A155 A Web-Based Application for Predicting the Fluvial Transport of Human Remains in the Sacramento River, California: Case Applications for Constraining Search Parameters for River Victims

Jazmin Borrayo, BA, California State University, Chico, Chico, CA; Eric J. Bartelink, PhD, California State University, Chico, Chico, CA; Colleen Milligan, PhD, California State University, Chico, Chico, CA*

Learning Objectives: After attending this presentation, attendees will understand how the web-based application, SacRiverSearch, can be used to predict search parameters for locating human remains within a riverine environment. Two historical case studies are used to illustrate the potential of the application to narrow search parameters for river victims.

Impact Statement: This presentation will impact the forensic community by discussing how SacRiverSearch can be used to predict fluvial transport distances of human remains in the Sacramento River of northern California if the location of entry into the river is known. The application can be used to constrain a search area, resulting in a more rapid recovery of a river victim.

Abstract Text: SacRiverSearch is a web-based application developed as a tool for search and rescue teams and law enforcement to locate a victim within the Sacramento River (between River Miles 199-80). The model is built using hydraulic simulations developed for the Army Corps of Engineers Hydraulic Engineering Center River Analysis System (HEC-RAS). Although originally developed for flood control, the HEC-RAS model was used to understand the movement of objects on the water surface (advective transport), which for this study, was rescue mannequins. The study area was divided into 20 sections, with three independent trial runs conducted per location for each flow rate condition. The deployment of rescue mannequins over multiple trials throughout major stretches of the Sacramento River was used to calibrate the model, simulating the transport of human remains. A python script used the velocities calculated by the HEC-RAS in an advective transport scheme and Global Positioning System (GPS) data from the mannequin trials were used to calibrate the transport model.

If the location of entry of a river victim is known, the closest river mile, the time since deposition in the river, and the general flow rate in cubic feet per second, or cfs (low< 6000 cfs; medium >6000-9000 cfs; high >9,000 cfs) can be selected within the application. A data set of 195,000 records was interpolated onto flow increments at 100 cfs increments to build a lookup table for the application. Once the location of entry, time since entry, and flow rate data are entered, the application generates a 95% prediction interval for human remains cases that are in the bloat stage, usually 3-4 days post-deposition. Searches for river victims within the first two days generally focus on a one-mile radius around the point of entry, given that little movement occurs on the river substrate until medium to high flow-rate conditions are met.

Two historical case studies are used to demonstrate how SacRiverSearch can be used to narrow down search parameters. A known drowning victim entered the Sacramento River under high flow rate conditions at river mile 90 in Knights Landing, CA. Given a two-day submersion interval, the 95% prediction interval extended six miles to river mile 84. The victim was found within a mile south of the point of entry and in the predicted search area. A second known drowning victim entered the Sacramento River under medium flow rate conditions at river mile 195.5 in Chico, CA. Given a six-day submersion interval, and assuming the body floated on day four, the 95% prediction interval was wide and extended to river mile 122. The actual distance traveled based on the recovery location was approximately one mile downstream. The large discrepancy in the distance traveled may be explained by interferences such as natural strainers, snags, grounding out, river eddies, or human infrastructure (e.g., pumps, fish traps). Thus, searches for river victims should first begin at the point of entry.

A156 From Scene to Screen: 3D Data Collection Options for Forensics

Jessica Cronin, MS, Angelo Coast Range Reserve, Willits, CA; Stephanie Melillo, PhD, Mercyhurst University, Erie, PA*

Learning Objectives: Documentation is a major component of scene processing in the forensic archaeology framework because spatial relationships provide evidence of context and association.[1] Technological innovation has produced a variety of options for spatial documentation, most recently as Three-Dimensional (3D) digital models of entire scenes. Attendees will learn about 3D scene scanning technology at a high and low price point. We provide quantitative data to compare accuracy and precision and to describe learning curves.

Impact Statement: We hope the information presented here will assist members of the forensic science community who are interested in incorporating 3D scene scanning into their documentation practices.

Abstract Text: Spatial documentation can manifest as physical or digital maps of evidence and, most recently, as 3D models of entire forensic scenes. Terrestrial Laser Scanners (TLS) are one extremely accurate and precise method of creating comprehensive 3D models of scenes using Light Detection and Ranging (LiDAR).[2] However, they are also incredibly expensive, ranging from $30,000 to $250,000, excluding software licensing requirements, which places this valuable form of documentation out of reach for many departments and agencies.[2] The cell phone application *Scaniverse* is another option for generating digital models of scenes that is completely free and requires no specialized hardware.[3]

This study aims to compare the performance of the Trimble X7 3D Laser Scanning System to the *Scaniverse* application.[4] Twelve volunteers scanned a mock crime scene three times using both modalities. Scan duration was recorded. At the end of each scanning session, volunteers completed a survey aimed at tracking the learning process and familiarity with the technology.

To quantify accuracy and precision, the point cloud generated during each scanning session (hereafter, test scans) were aligned to one extremely high-quality TLS scan that was selected to represent the true topology of the scene (hereafter, scene Truth). Next, the Cloud-to-Cloud distances between each test scan and the scene Truth were computed in CloudCompare (2.13.2 Kharkiv).[5] Accuracy was quantified as the average distance between a volunteer's test scans ($n = 3$) and the scene Truth, and precision quantified through variation.

Mean distances for the X7 test scans deviated from the scene truth by an average of 1cm, compared to 5-7 cm for the *Scaniverse* app. The X7 was also found to be significantly more precise than Scaniverse ($F = 379.9$, $p << 0.001$) with a variance of $1.46 \times 10^{-0.5}$. The variance for the *Scaniverse* app was 0.005. No learning curve, in the form of decreasing mean distances over three trials, was detected for either modality. Neither modality was reported by participants as being easier to use.

Ultimately, it is up to the discretion and needs of the practitioner to determine if the *Scaniverse* application is an acceptable option for 3D data collection. Future research should focus on data collection with LiDAR-capable mobile devices, which have already begun to be explored in forensic contexts.[2,5-8]

A157 Virtual Bonescape: Integrating Two Recovery Methods, Virtual Re-Association of Fragmented Remains and Scene Reconstruction, in a Disaster Victim Identification Context

Lise Malfroy Camine, DDS, IRCGN, Pontoise, Ile-de-France, France; Silke Grabherr, PhD, CURML, Lausanne, Vaud, Switzerland; Negahnaz Moghaddam, PhD, Netherlands Forensic Institute, The Hague, Zuid-Holland, Netherlands; Vincent Varlet, PhD, SHIFT / CURML, Lausanne, Vaud, Switzerland*

Learning Objectives: Attendees will learn how two fundamental recovery strategies—an archaeological grid and drone-based geolocation—can be applied and evaluated in simulated forensic contexts involving fragmented human remains. They will also gain practical insights into Virtual Re-Association (VRA) techniques using Computed Tomography (CT) imaging and 3D modeling to reconstruct and analyze fragment dispersion at disaster scenes.

Impact Statement: This presentation will enhance forensic practitioners' competence by comparing field recovery techniques in terms of efficiency, precision, and integration with digital tools. It will support performance improvement in Disaster Victim Identification (DVI) by demonstrating how integrating traditional archaeological methods and drone-based field documentation with advanced imaging and virtual modeling can optimize the DVI mission efficiency and the understanding of the event in mass fatality situations.

Abstract Text: In mass fatality incidents, the recovery and re-assocation of fragmented human remains (FHRs) remain foundational to Disaster Victim Identification (DVI) efforts.[1-3]

This study revisits two fundamental yet contrasting scene recovery strategies—a deployable archaeological grid and drone-based photogrammetry—to evaluate their application in the documentation and geolocation of dispersed FHRs.[4,5] It also assesses the integration of these methods into a virtual re-association (VRA) workflow that uses CT-scanning and 3D modeling to match bone fragments and reconstruct their dispersion pattern, forming a "Virtual Bonescape".[6,7]

Two experimental setups, using porcine models, simulated explosive fragmentation and manual scattering. The first involved the detonation of a Sus scrofa specimen, followed by systematic recovery using an adapted archaeological grid, CT-scanning of collected fragments, and VRA analysis, using Mimics® and CloudCompare® softwares. The second scenario used manually fragmented and color-coded long bones scattered over a field, documented with the same archaeological grid and an alternative method using coded targets and drone imaging, followed by CT-scanning and VRA with the same protocol, and a scene reconstruction using Agisoft Metashape Professional software.

The archaeological grid method appears to be cost-effective and sufficiently in confined or constrained environments but slow and error-prone in large or urgent scenarios. The drone-based approach enabled faster recovery, with efficient 3D scene modeling, though weather impacted target detection. Both methods supported the Virtual Re-Association using CT scans of the fragmented remains, thus offering a non-destructive, accurate alternative to DNA analysis. Both methods supported spatial dispersion virtual reconstruction.

This study demonstrates that while drone-based documentation accelerates the recovery process and enhances geospatial accuracy, the archaeological grid remains a valuable tool in settings where drone use is limited. The integration of both methods with VRA lays the groundwork for retrospective scene reconstruction, offering deeper insights into event dynamics, such as victim-perpetrator positioning, fragmentation patterns, and taphonomic alterations.[8-10]

By returning to the basics of systematic documentation and adapting them with digital tools, this study supports a refined, multidisciplinary approach to managing complex DVI scenarios involving fragmented remains. The proposed methods may improve disaster victim identification efficiency, reduce reliance on destructive techniques, and ultimately contribute to the ethical and efficient return of victims to their families.

A158 The Impact of Decomposition Stage, Hypoxia, and Enclosure in a Class C Motorhome on the Morphological Trajectory of Fire-Exposed Human Remains

Christiane I. Baigent, PhD, Colorado Mesa University, Grand Junction, CO*

Learning Objectives: After attending this presentation, attendees will better understand the complex pattern of skeletal change yielded by a multivariable (high-altitude hypoxia, Class C Motorhome [CCM], decomposition stage) burn environment.

Impact Statement: This study will impact the forensic science community by describing the thermal alteration of human remains in the underrepresented high-altitude hypoxic environment within a CCM and the resulting burn, fracture, and color change patterns that diverge from those most frequently described in the literature.

Abstract Text: Colorado Mesa University's Forensic Investigation Research Station (FIRS) high-altitude satellite facility (FIRS-TB40) is located in Park County, CO, 9800 feet Above Mean Sea Level (AMSL). The region has a large "invisible population," primarily composed of veterans living off grid in remote areas of the county. CCMs provide popular housing in the region; older models are affordable, readily available, can reach remote locations, and are small and easy to conceal. Because this population seeks solitude and anonymity, postmortem discovery may be protracted. Variables such as Colorado's seasonal wildfires, high-risk behavior, and interpersonal violence contribute to cases involving burnt human remains, but the relationship between hypoxia, the CCM burn environment, and heat exposure throughout the Postmortem Interval (PMI) is not well understood.

Four human donors opted into this study. Donors represented phasic stages of decomposition: fresh (PMI< 24-hours); advanced outdoor (PMI=six-weeks); advanced indoor (PMI=eight-weeks); and skeletal (PMI=four-years). Donors were individually placed in CCMs. Fires were ignited in the engine bay and allowed to burn until they self-extinguished (~45 minutes). Remains were recovered following Symes et al.[1] Color change, burn and fracture pattern, and osseous architecture were assessed following Symes et al.[1,2]

Summarily, burn pattern, color change, and fracture type both mirrored and diverged from those described in the literature.[2,3] In all cases, regions classified as "first to burn" (frontal, proximal/distal long bones) demonstrated high survivability, while "last to burn" regions (os coxa, radial, ulnar, and femoral diaphyses) demonstrated poor survivability.[2] Color change lacked organized transition zones and heat lines, and discoloration was mottled, complex, and chaotic. With the exception of the skeletal case (PMI four years), color change was characterized by blue-gray mottling and endosteo-trabecular char. Degree of cranial fracture and skeletal loss shared a relationship with PMI. Extensive fragmentation, delamination, and char were associated with the fresh remains, advanced decomposition (six weeks) presented modest fragmentation, retention of the frontal bone, but moderate ectocranial delamination. Advanced decomposition (8 weeks) presented the same pattern but lacked ectocranial delamination. The greatest survivability of skeletal elements was observed in the skeletonized remains. Color change was a homogenous yellow with blue/black endosteal char. Fragmentation was mild-moderate throughout the skeleton. When fractures occurred, they presented modified morphology. Complete transverse resulting in diaphyseal failure was most frequently observed. Curved transverse fractures were limited to small-area, superficial, hairline fissures. Longitudinal fractures were associated with soft-edged, curved warping as opposed to clean, sharp osteonal failure.

This study suggests that PMI-specific heat treatment yields unique burn signatures and supports previous study.[3] Divergence from well-described burn, discoloration, and fracture patterns were observed in this study. This may be artifact of the hypoxic environment, containment within a CCM, or a cross-section of variables. These data support the growing assertion that temperature-centric models of burned bone discoloration are overly reductive.[4] Future study is necessary to more thoroughly and accurately describe phasic postmortem burns in a hypoxic, CCM environment.

A159 Gull (*Laridae*) Scavenging and Dispersal of Pig (*Sus Scrofa*) Remains on Appledore Island, Maine

*Austin S. Millwood, B.A., B.S. *, Boston University, Gaffney, SC; James Pokines, PhD, Boston University, Boston, MA*

Learning Objectives: Attendees will gain an understanding of the extent of gull (Laridae) bone dispersal distances and patterns and soft tissue feeding in comparison to other avian scavengers. Attendees will also learn about the behaviors of gulls and their potential to scavenge.

Impact Statement: Attendees will learn how gull feeding and dispersal patterns may affect forensic search and recovery efforts where these taxa may have been active. This includes information on the possible expansion of search radii.

Abstract Text: Avian scavenging is an understudied phenomenon within forensic contexts. Bird flocking behaviors allow these taxa to consume a large amount of tissue, while flight ability provides for a large degree of bone dispersal. Most existing research has focused on taxa, including vultures (Cathartidae) and crows (Corvidae), leaving other likely scavengers unconsidered. One such family of avian scavengers is gulls (Laridae). Gulls have become increasingly reliant on human-generated refuse for food over the past several decades. As a result, gulls have had greater contact with humans, making them a potentially more important taphonomic agent at outdoor forensic scenes. The present study examined gull scavenging behaviors and the extent of bone dispersal. The authors hypothesized that gull dispersal distances would be greater than those of other avian taxa, and that the directionality of the dispersal would correlate with nesting locations.

The present study was conducted on Appledore Island, Maine, in the Isles of Shoals. During the summer months, Appledore has large breeding colonies of herring gulls (*Larus argentatus*) and great black-backed gulls (*L. marinus*). The study consisted of eight two-week trials with 2 pig (*Sus scrofa*) heads and 12 pig femora placed at each of two locations, with shifting of deposition locations to reduce habituation by the gulls. Tile Pro Tags were attached to each femur; these tiles emit an auditory alarm, when activated, which aids in the recovery process.[1] Motion-activated trail cameras recorded the scavenging progression at each site, and dispersal distances, dispersal direction, and bone mass were recorded at the end of each two-week trial.

While scavenging, the gulls showed both intra- and inter-species aggressive behaviors, with the great black-backed gulls more often acting as the aggressor. Despite this, there were many instances of group scavenging, sometimes with both species. The gulls were noted to feed more continuously toward the beginning of each trial, with instances of scavenging generally decreasing throughout each trial. The gulls were recorded scavenging during both day and night and continued scavenging during episodes of rain. While scavenging, the gulls did not attempt to breach the skin of the pig heads, despite previous studies demonstrating the capability to tear skin; the gulls instead focused on areas of already exposed subdermal tissue. The dispersal distances of the remains varied widely throughout this study's trials, but the maximum distances for femora were greater than typical maximum distances reported for black vultures (*Coragyps atratus*) and turkey vultures (*Cathartes aura*). The average dispersal distances were comparable to those of vultures. Maximum dispersal distances for gulls exceeded 44 m for pig femora and 19 m for pig heads, indicating that search methods for scenes where gulls may have been involved should have a minimum radius that encompass these distances. At some trials, the Rayleigh z scores indicated significance for the directionality of the dispersal of remains. The directionality of the dispersal mainly was toward areas with minimal to no woody brush where the environment was not uniform.

A160 Patterns of Vulture Scavenging in West Central Florida

Tuesday M. Frasier, MS, USF-IFAAS, Tampa, FL; Erin H. Kimmerle, PhD, IFAAS, USF, Tampa, FL*

Learning Objectives: This oral presentation will introduce attendees to different patterns in scavenging between microenvironments. Attendees will be presented with videos and photographs that demonstrate these patterns of behavior in action. Following this presentation, attendees will be able to identify modifications to bodies and sites resulting from vulture scavenging.

Impact Statement: This presentation will impact the forensic community by establishing clear patterns of behavior for vultures across two microenvironments, which impacts how vultures choose to interact and scavenge cadavers. This provides important information for site variation, modification, and the alteration of the scene by non-human agents.

Abstract Text: The purpose of this presentation is to identify patterns in behavior for vultures between two microenvironments and in response to human activity. When it first began operation, the University of South Florida Facility for Outdoor Research and Training (USF-FORT) was in a rural area of Pasco County, approximately 25 miles from the urban center. Throughout the next six years, the area became increasingly urban with construction adjacent to the USF-FORT, resulting in an increased human presence near the research site. At USF-FORT, the American Black vulture was responsible for most vulture scavenging, while the Turkey vulture was present in fewer numbers. Two types of microenvironments were utilized at USF-FORT: a dry grassy field with full sun exposure and a vernal pond with tree coverage that flooded seasonally. A total of 107 donors were placed at the USF-FORT from October 2017 to April 2022. Of these donors, 96 individuals were placed in the open field, while 11 were placed in the vernal pond. Vultures scavenged 35.3% (n=34) of the field donors and 90.1% (n=10) of the donors placed in the vernal pond. This study investigates the preferences for each microenvironment and explored how vultures interacted with the donors at the site.

It was found that vulture behavior is different across the USF-FORT site. Statistical tests ($p < .001$) indicated that there is a significant association between microenvironment and vulture scavenging. While vultures did demonstrate a preference for placement site, microenvironment was not significant for the arrival of vultures (p=.428) or the number of times vultures scavenged the donor (p=.265). When interacting with the USF donors, the vultures most often modified cadavers by moving the limbs. These modified areas became discolored and decomposed at a faster rate compared to surrounding tissue. Over time, their behavior became more aggressive as vultures rotated the body and disarticulated skeletal elements, which did not vary between microenvironments. In addition to modifying the physical remains, vultures modified the terrestrial site through trampling. This presents a problem as vultures not only modify the context of how donors were placed on the surface but also disturb the ground surface immediately surrounding the donor.

The findings at USF-FORT suggest that vultures are highly adaptable through behavior modification in response to environmental stimuli, and that scavenging is done with intention. The preference by vultures for donors placed in the vernal pond suggests that the woods may offer some protection and security to vultures as they scavenge, especially when there is an increase in human activity in the immediate area. Patterns in vulture scavenging may be affected by rural versus urban environments. When scavenging, vultures modify bodies to increase the rate of decomposition to more easily scavenge upon subsequent visits. Vultures are very influential when it comes to the modification of cadavers and their placement sites. Further research into the modification of vulture behavior in rural versus urban environments should be further explored outside of Florida using a larger sample size and examine variables such as weather, season and species.

A161 An Assessment of Standard Operating Procedures for Forensic Anthropology at Accredited United States Laboratories

Marion Davidson, MSc, University College London, Baltimore, MD; Allysha P. Winburn, PhD, University of West Florida, Pensacola, FL; Taylor M. Flaherty, PhD, University of Nevada, Las Vegas, Detroit, MI*

Learning Objectives: After attending this presentation, attendees will have a comprehensive understanding of the Standard Operating Procedures (SOPs) for forensic anthropological analysis in American National Standards Institute (ANSI) National Accreditation Board (ANAB) -accredited facilities. Additionally, this presentation will highlight areas of high variability and offer insight as to how laboratories might improve standardization within and across the field.

Impact Statement: This presentation will impact the forensic science community by presenting the updated findings from an assessment of forensic anthropology standard operating procedures. This presentation will assist in the continued discussion of the professionalization of forensic anthropology by providing insight into how ANAB-accredited laboratories work to ensure quality and reliability in their forensic judgments and decisions.

Abstract Text: The 2009 National Academy of Sciences (NAS) Report highlighted concerns over the extensive heterogeneity in forensic science practices and training as well as highlighted the need for forensic analyses to be accurate, reliable, and free from the potential impact of irrelevant contextual information.[1] In response, forensic anthropologists have been working to develop and improve SOPs, best practice recommendations, and quality assurance protocols. As the use of standard procedures by multiple laboratories is necessary to reduce variability and in turn improve reliability, this study was designed to assess the homogeneity of SOPs from forensic anthropology laboratories accredited under the ANAB.[2]

First, the ANAB Directory of Accredited Organizations was searched with the term "anthropology" to identify relevant facilities. At the time of data collection, five laboratories were identified as possessing a Certificate of Accreditation for Forensic Anthropology. Heterogeneity was revealed at this structural level, as two labs were accredited to International Organization for Standardization (ISO) 17020 and three were accredited to ISO 17025. Additionally, the number of accredited components for each lab ranged from 8 to 12, with all labs accredited to 7 components, including biological profile and medicolegal significance. This information is crucial as these factors will impact the necessity for particular SOPs.

Next, SOPs were accessed as publicly available documents or requested directly from the laboratory. These documents were examined and coded for the presence of various practices. Analysis included the examination of broad forensic science trends (e.g., competence and proficiency, documentation, reporting, testimony, and human factors considerations) and specific forensic anthropological trends (e.g., biological profiling, trauma analysis, and method selection). Results reveal a combination of homogeneity and heterogeneity at several structural levels. For example, while all assessed labs discuss the importance of effective testimony, only one provides direct guidance as to what is considered appropriate or inappropriate testimony. Additionally, while all labs require that selected methods are validated, the requirement of this validation varies between occurring internally or externally, with only one lab providing specific methods that are considered acceptable.

Accredited forensic anthropology labs are disciplinary leader, whose approaches guide not only their staff but also other practitioners seeking to codify their lab protocols to a high standard. As such, SOPs should be publicly available or freely shared to maximize transparency, and future research should consider expanding to non-accredited forensic anthropology labs.[3] This research can contribute to the identification of areas where substantial progress in standardization has been made as well as highlight aspects that require more improvement. Once identified, the reasons for this heterogeneity can be examined (e.g., sole practitioner labs) to allow for these limitations to be properly addressed. Finally, as this coding system was modeled after a similar analysis in friction ridge examination, there is potential for collaborative and interdisciplinary discussion among forensic service providers that can ultimately contribute to the improvement to the overall forensic science process.[4]

A163 Standards Development in Forensic Anthropology: Progress and Updates From the OSAC and ASB

Eric J. Bartelink, PhD, California State University, Chico, Chico, CA; Julie M. Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: After viewing this presentation, attendees will be updated on the status of proposed standards, best practices, and technical reports drafted by the Organization of Scientific Area Committees' (OSAC) Forensic Anthropology Subcommittee and those drafted and published by the American Academy of Forensic Sciences' Standards Board's (ASB) Anthropology Consensus Body.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of forthcoming and existing standards, Best Practice Recommendations (BPRs), and Technical Reports (TRs) in forensic anthropology, including publication by the ASB and placement on the OSAC registry. This presentation further highlights the need for the forensic anthropology community to engage in the development of consensus standards.

Abstract Text: The OSAC, administered by National Institute of Standards and Technology (NIST), was established in 2014 to facilitate the development of national standards for forensic science. The Forensic Anthropology Subcommittee (FASC) is one of four subcommittees under the Medicine Scientific Area Committee and includes representation from academia, medical examiners' offices, government labs, and legal, quality assurance, and human factors. Each subcommittee is charged with drafting proposed standards, which are then submitted to a Standards Developing Organization (SDO) for further development and publication. Once draft standards are listed on the OSAC registry, they are distributed to the ASB, established in 2015 as an American National Standards Institute (ANSI) -accredited SDO, to publish forensic science standards. The Anthropology Consensus Body (CB) of the ASB includes representation from various interest groups, including academia, governmental and non-governmental users, general interest, and producers. Once published, the FASC reviews the standard for technical merit, makes a recommendation for its placement on the OSAC registry, and submits it to the Forensic Science Standards Board (FSSB) for final approval.

This presentation will describe the differences between standards, BPRs, and TRs; summarize recent standards development activities by the OSAC and the ASB, including ASB standards currently on the registry; ASB standards eligible for the OSAC registry; proposed documents that are currently open for public comment or in comment adjudication at the ASB; and OSAC proposed standards in progress. As of August 2025, ASB has published 11 standards and 1 best practice. The best practice and three of the standards are currently on the OSAC registry, and two additional standards are in review for the registry by the FSSB. Three BPRs and one TR are being drafted by the ASB, four proposed standards are currently under development and nearing completion by the OSAC FASC, one OSAC proposed standard was submitted to the ASB for publication and two for development as a joint venture, and two published ASB standards are in revision for second editions.

A164 Normalizing Discussions of Mental Health in Forensic Anthropology

Katharine Pope, MA, SNA International supporting the DPAA mission, Fruitland, MD; Erin B. Waxenbaum, PhD, Northwestern University, Evanston, IL*

Learning Objectives: After attending this session, attendees will have an appreciation for situations that create stress and vicarious trauma within the field of forensic anthropology, factors that limit mental health discussions, and the value of addressing this issue directly for the health and wellbeing of practitioners.

Impact Statement: Attendees will appreciate the impact of more open discussions of mental health considerations among those who engage in forensic anthropology casework. This will inform forensic anthropology stakeholders in planning and appreciating tools and opportunities needed for their constituents in the workplace.

Abstract Text: Traditionally, forensic anthropologists spent their time recovering and analyzing human remains in closed, secure environments such as clandestine graves and academic labs. However, the field has expanded significantly; as such, forensic anthropologists are now more proximate to the people and events associated with their casework. Today, forensic anthropologists may be found working alongside forensic pathologists in autopsy suites, participating in mass disaster responses and training, and engaging directly with families in missing persons interviews for identification efforts. This expanded role brings the practitioner into closer and repeated contact with death, grief, and trauma. While many forensic disciplines have addressed the impact of vicarious trauma in their work, the specific effects on forensic anthropologists remain largely underexplored.

The authors conducted a survey to better understand how forensic anthropology practitioners acknowledge or support their mental health and what aspects of their casework they find personally triggering or stressful. Participants answered questions about professional experience with forensic anthropology, personally triggering casework, and managing work-related stress.

A total of 114 participants answered questions about their experience with triggers, personal/professional stress, and coping mechanisms. Several participants offered personal testimonials in open text responses about mental health experiences through their career in forensic anthropology. Participants ranged in age, were predominantly female identifying (70.1%), partnered for five or more years (52.6%), held a doctorate degree (59.6%), and many are board certified (D-ABFA) in forensic anthropology (30.7%). The majority of participants were employed primarily in a medical examiner or coroner setting (37.7%), while many were employed across multiple modalities including academic/university settings as well as private or military institutions.

Participants described being most triggered by cases involving children/child abuse and cases that result in their testimony at trial. Stress was noted as highest surrounding personal finances, work/life balance, engagement with work supervisors, and speaking with family/friends of case related decedents. Many respondents noted feeling supported by their coworkers and supervisors, and a majority noted their employer provides exposure to mental health wellness programs. However, 52% of participants mentioned feeling comfortable discussing their mental health concerns and 57% sought professional support for work-related stress/anxiety. Participants highlighted compartmentalization, peer/coworker support, and exercise/sports as relevant and positive mechanisms to cope with work related stress. Overall, 73% of respondents said they would still choose to pursue forensic anthropology knowing what they know now about the stress and associated triggers of the field.

hese findings underscore both ongoing mental health challenges and resilience of the forensic anthropology community. Despite regular exposure to emotionally charged and potentially traumatic casework, many practitioners demonstrate a strong commitment to their profession, supported by a range of coping strategies and institutional resources. The data also highlight significant gaps in mental health support, communication, and normalization of mental health discussions within the field. Continued efforts to acknowledge, research, and address the psychological impacts of forensic anthropology practice are essential to fostering a healthier, more sustainable professional community.

A165 An Examination of the Medicolegal Processes Relating to Native American Repatriation

Arielle Reich, MA, University of Illinois Urbana-Champaign, Urbana, IL; Cris E. Hughes, PhD, UIUC, Urbana, IL; Marynia A. Kolak, PhD, University of Illinois at Urbana-Champaign, Urbana, IL; Catherine Discenza, BS, University of Illinois Urbana-Champaign, Urbana, IL; Krystiana L. Krupa, MSL, University of Illinois Urbana-Champaign, Champaign, IL; Jenny L. Davis, PhD, University of Illinois Urbana-Champaign, Champaign, IL*

Learning Objectives: After attending this presentation, attendees will understand how state medicolegal systems may reconcile state and federal law regarding how to assess the expected movement of Native American Ancestors encountered by coroner/Medical Examiner (ME) offices. Further, by exploring a state-level case study conducted in Illinois, attendees will learn how this expected investigative pipeline (as outlined legislatively) compares with the actual pipeline of how Native American Ancestors move through the medicolegal system.

Impact Statement: This presentation will impact the forensic science community by providing a model for evaluating medicolegal workflows under the consideration of both state legislation and the Native American Graves Protection and Repatriation Act (NAGPRA; 25 U.S.C. § 3001 [1990]), highlighting areas for improvement to support more consistent practices.[1]

Abstract Text: The overlap between Native American repatriation efforts and medicolegal systems remains understudied by the forensic science community, despite coroner/ME offices often serving as the first point of contact when unidentified human remains are encountered. Further, identification of remains as Native American Ancestors requires specialized expertise and legal awareness that may not be uniformly present across jurisdictions. Sufficient legal and procedural guidance/training is necessary to ensure the opportunity for repatriation; however, it was only in 2023 that the Department of the Interior published a Final Rule on NAGPRA (effective 2024) that explicitly confirmed, for the first time, that coroners/MEs are agencies that should consider NAGPRA's applicability in their work (NAGPRA Systematic Processes, 2023). Through a combination of policy analysis and first-hand accounts from medicolegal practitioners, this research contributes to broader discussions on accountability by the forensic community in the repatriation process.

Given variation in medicolegal systems and state laws regarding human remains, a state-level approach was necessary. Illinois serves as a case study; it has a mixed county-coroner system with one coroner office in each county apart from Cook County, which has an appointed ME.[2] According to the Illinois Human Remains Protection Act (HRPA; 20 Illinois Compiled Statutes [ILCS] 3440), when human remains are encountered unexpectedly, the coroner/ME assumes jurisdiction and is responsible for determining medicolegal significance and time since death, while the Illinois Department of Natural Resources (DNR) is responsible for estimating the ancestry of non-forensic cases and conducting the repatriation of remains identified as Native American Ancestors.

To understand how the system works in practice, a survey was distributed to all 102 Illinois coroner/ME offices regarding human remains casework (one per county) with questions relating to relevant state and federal laws. Respondents with complete/near complete surveys used in analyses include coroners/MEs (n=32), chief deputy coroners/MEs (n=5), detectives/investigators (n=2), and one respondent who did not include their job title. These 40 respondents are each from distinct counties, thus representing 39% of Illinois counties (40/102).

Some key findings include greater familiarity with HRPA than NAGPRA (Wilcoxon signed-rank test: p=0.0007). Further, greater familiarity with NAPGRA indicated a higher likelihood for a coroner/ME office to have protocols for determining Native American ancestry (Wilcoxon rank sum test: p=0.01818). Regarding the involvement of the Illinois DNR (as outlined in HRPA), only 45% of respondents said that they contact DNR for assessing Native American ancestry of skeletal cases, with the existence of protocols as a driving factor (Fisher's exact: p=0.005132) but not familiarity with either NAGPRA (Fisher's exact: p=0.7446) or HRPA (Fisher's exact: p=1). Lastly, there was a clear trend in respondents indicating a desire for training in and resources for relevant legislation, even without a direct survey prompt (41%).

Findings show the need for clearer legal/policy standards, increased training, and interagency/personnel coordination, thus facilitating the identification and repatriation of Native American Ancestors encountered by medicolegal agencies. The project offers a model for policy evaluation that can be applied beyond Illinois, with the ultimate goal of improving repatriation pathways in forensic contexts across each state.

A166 Assessing Forensic Significance and Ethical First Steps at the West Tennessee Regional Forensic Center

Christine Bailey, MA, University of Tennessee, Knoxville, New Market, TN; Diana Messer, PhD, West Tennessee Regional Forensic Center, Memphis, TN; Devin L. Adcox, MA, University of Tennessee Knoxville, Knoxville, TN*

Learning Objectives: After attending this presentation, individuals will understand one approach for re-evaluating cases for forensic significance. Potential next steps will be outlined for cases where forensic significance is unclear and for cases that fall outside the authority of the medicolegal system.

Impact Statement: This presentation will provide attendees with a strategy for re-evaluating the forensic significance of remains housed in medicolegal offices and provide suggestions for next steps using a case study.

Abstract Text: Human remains of uncertain forensic significance occupy a liminal space within medicolegal investigation. They are neither clearly associated with a known missing person nor definitively identified as anatomical, historical, or archaeological in origin. This ambiguity presents a unique challenge for forensic anthropologists who must assess whether such remains warrant further medicolegal investigation.

While initial visual assessments are standard, recent research demonstrates that determining forensic significance is not always straightforward and may require additional testing and contextual evaluation.[1] Once remains are deemed not forensically significant, medical examiner's offices often lack clear protocols for their final disposition.

A comprehensive re-assessment of 47 cases was conducted at the West Tennessee Regional Forensic Center (WTRFC) to evaluate their forensic significance. The goals were to: (1) identify cases previously classified non-forensically significant cases that may warrant additional testing, and (2) recommend next steps for remains falling outside the medicolegal system.

The condition of the remains and available contextual information varied. While some cases had formal case numbers, others were uncataloged, prompting a new numbering system. Upon reanalysis, 21 individuals (45%) lacked sufficient information to confidently determine forensic significance. Radiocarbon analysis, as demonstrated by Getz and colleagues, is an effective method to determine whether remains date to the modern forensic era and is recommended for these cases.[1]

Of the remaining 26 cases, one was determined to be a "trophy" skull based on taphonomic and contextual information. Four individuals were determined to be anatomical specimens due to the presence of mounting hardware and/or other modifications. Eleven individuals were identified as possibly prehistoric based on burial context, cranial modification, and dental traits, while ten individuals were recovered from a historic cemetery on President's Island in Memphis, TN.

Non-forensically significant remains pose complex legal and ethical questions. Prehistoric remains trigger legal obligations under the Native American Graves Protection and Repatriation Act (NAGPRA) which requires consultation with affiliated tribes and repatriation of ancestral remains.[2] Although anatomical, "trophy", and historic remains may not fall under specific legislation, they still warrant ethical consideration. Medicolegal offices are responsible for treating all human remains with dignity, yet they have been largely excluded from recent conversations on managing legacy skeletal collections.[3-5]

The President's Island cases illustrate how medicolegal offices can address such remains through proactive community engagement, even without a legislative mandate.[6] Based on the site's historical context and its connection to the antebellum South, these individuals are likely African American.[7] The START model, developed by Domeischel and Neller, outlines a five-stage framework emphasizing incremental progress and community engagement.[8] This model has been implemented at WTRFC and will continue to guide resolution efforts.

Medicolegal offices must maintain accurate records, pursue further testing when needed, and develop ethical pathways for remains outside their legal scope. Forensic anthropologists play a vital role in this process and have a professional obligation to advocate for appropriate evaluation, engagement, and respectful disposition.

A167 Ethics and Preventive Forensics in the Face of Violent Deaths: WWCD (What Would Clyde Do)?

Derek Congram, PhD, Simon Fraser University, San Jose, San Jose, Costa Rica; Nicholas V. Passalacqua, PhD, The Ohio State University, Hilliard, OH; Marin Pilloud, PhD, University of Nevada, Reno, NV; Hugo Rodriguez-Almada, MD, University of the Republic, Montevideo, Montevideo, Uruguay; Gina O. Hart, MA, Jefferson Parish Coroner's Office, Harvey, LA; Mark F. Skinner, PhD, Simon Fraser University, Burnaby, British Columbia, Canada*

Learning Objectives: By invoking the memory of the late Clyde Snow, attendees will learn how the collective experience of many section members has taught us what genocide, crimes against humanity, and war crimes look like. They will be reminded that one of the principal benefits of death investigation is that it can inform public policy and action to stop and prevent violent deaths. The presentation will define important terms including ethics, neutrality, and objectivity and relate them to contemporary practice.

Impact Statement: This presentation will impact the forensic science community by reminding colleagues of our acquired knowledge and of our ethical responsibilities to share this knowledge for preventive, rather than only reactive, purposes. It will clarify frequent misuses of terms that relate to how and when we use the knowledge that we produce through our work, with recommendations for how we can have greater impact on future policy and practice.

Abstract Text: Many veterans of the Anthropology Section have seen genocide, wide-scale, and systematic killings up close. We have excavated the cemeteries and mass graves of Argentina, Colombia, Guatemala, Peru, the Democratic Republic of Congo, Chad, the former Yugoslavia, Iraq, and Spain. We have documented our *in situ* observations: both hands behind the back, tied together by a ligature; cloth over the eyes and knotted behind the head; the striped pattern of the dress of a woman and three children that are clustered together in a corner of the mass grave. We have mapped the concentrations of shell cases at the edges of the graves before collecting them as evidence. In these places, in Cambodia, and elsewhere, we have held the crania of those exhumed in our hands and documented the entrance and exit wounds, described the splintered ribs that sometimes show semicircular defects, and we have reconstructed the fragmented humeri and femora to try to interpret the direction, timing, and causal agent of the trauma. We have profiled the victims: young and old men mostly, but also subadults in pants, dresses, and rubber boots, and a woman with the bones of a 6-month-old fetus under her dress and overlying her pelvic cavity. We have debated if we, as forensic anthropologists, are the right experts to document the clothing and personal objects that are evidence of their identities and the crimes that were committed- combatants or non-combatants, Muslims, Kurds, or Catholics, union members, migrants, and many (more than we like to admit) who we did not individually identify. But if not us, then who?

We are proud of our work and congratulate ourselves for it, even if it comes years or decades after crimes were committed. We talk about ethics and objectivity—values we all are beholden to by virtue of our AAFS membership—and we extol humanitarian work, typically characterized by neutrality. What we have not talked about is whether we can be both ethical and neutral at the same time. We have also failed to talk about how to use what we know to prevent, or at least stop, mass and systematic killings when they are ongoing.

This presentation will provide a brief overview of the work of AAFS Anthropology section members in places of wide-scale human rights abuses, war crimes, crimes against humanity, and genocide, an application pioneered and promoted for decades by former member Clyde Snow. It will remind listeners of how Snow advocated three goals for this work: (1) to identify and return the remains to family and community members for proper burial; (2) to collect evidence in a way that it will be admissible for judicial proceedings; and (3) to set the historical record straight. These days, we are witness to crimes similar to those that we have investigated, but which are ongoing now. We will ask listeners to respond to, "What Would Clyde Do," and ask if we should be doing just that.

Ethics; Preventive Forensics; Clyde Snow

A168 Language at the Border: Changing Our Language Changes Our Perspective

Makenna Mizell, BA, University of Indianapolis, Indianapolis, IN; Chastidy A. Gilbert, BA, University of Indianapolis, Rochester, MN; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN; Amandine Eriksen, PhD, University of Indianapolis, Indianapolis, IN; Lillian Bucher, BS, University of Indianapolis, Indianapolis, IN; Frankey Leggio, MS, University of Indianapolis, Indianapolis, IN*

Learning Objectives: After attending this presentation, attendees will gain a clear understanding of how language shapes the perception of migration and the lived experiences of migrants along the United States southern border. Specifically, they will learn how terminology commonly used in both forensic and humanitarian contexts can influence public perception and the dignity afforded to migrants.

Impact Statement: This presentation will impact the forensic community by enhancing their ability to engage with humanitarian fieldwork in a more ethically and culturally informed manner through the promotion of critical reflection on the language used to describe migrants and associated artifacts.

Abstract Text: The words professionals use to describe migration along the United States southern border strongly influence how one perceives the situation. The words and phrases used can directly impact the people involved by reinforcing harmful stereotypes. The language choices not only reflect but actively assist in shaping public understanding. Forensic anthropologists are actively providing archeological services aimed at locating migrants who perished in their journey across the border and osteological examinations to assist in positive identifications. Forensic anthropologists are academically trained as anthropologists, which emphasizes the importance of a holistic approach to humanity. Continuously evaluating the terminology used in sensitive situations, like migration across the United States-Mexico border, reflects the cultural and linguistic training anthropologists receive and acts to avoid any unintentional adverse undertones.

The University of Indianapolis Beyond Borders Humanitarian Forensic Science Team travels annually to the Texas Borderlands to assist local authorities with large-scale search and recovery operations in the remote wildlands. The goal is to search for individuals who may have died along clandestine routes so they may start the identification process and be returned to their families or home countries. Locating active migrant pathways in remote areas is accomplished by finding their discarded items, which are often described by using the term "trash." "Trash" is a negative term associated with filth and low value. We propose adopting a more neutral term, like "artifact," to describe these items. The term artifact is also appropriate as it emphasizes the importance of these items to the scientists working to reconstruct human behaviors in forensic contexts.

This presentation will explain how "artifacts" are used in the search and recovery context to locate clandestine pathways and reconstruct migrant activities by using examples from the January 2025 mission to the Texas Borderlands. A thoughtful and deliberate shift in the language associated with migration is not new. For example, the shift to the term "migrant" was a way to restore dignity and humanize individuals crossing the border. Additionally, recognizing the phrase "migrant crisis" implies the problem is with the migrants themselves and ignores the root cause of the necessity for migration. A switch from "trash" to "artifact" provides a broader understanding of what these items are- evidence of migration, struggle, and survival. This terminology shift recognizes the value of artifacts in a search and recovery context and humanizes the objects at the same time.

Language; Migrants; Border

A169 Preventing a Repeat of the Past: Ethical Considerations in Data Collection and Use in the Age of Artificial Intelligence and Machine Learning

Ashley C. Smith, MSc, University of Toronto, Toronto, Ontario, Canada; Eman Faisal, MSc, University of Toronto, Toronto, Ontario, Canada*

Learning Objectives: After attending this presentation, attendees will learn and gain a greater appreciation of the ethical issues surrounding the collection and use of data when developing Machine Learning (ML) models with a goal of ensuring data curation quality and decedent/familial-informed consent is a primary consideration in present and future research.

Impact Statement: This presentation will impact the forensic science community by bringing the discussion of how datasets are developed, curated, and used by artificial intelligence models in forensic anthropology and bringing them back to the basics through the discussion of ethical considerations in relation to data quality and accuracy, and decedent-informed consent.

Abstract Text: While it is impossible to predict the future, it is equally impossible to envision the future of forensic science, and specifically anthropology, where ML does not play a major role as decision support tools. In order for the various ML models to grow in a scientifically valid, effective, and efficient manner, accurate and ethical datasets are required. The history of anthropological methods reveals that most of these methods were built upon skeletal collections that are of dubious ethical provenance and may not have accurate life histories associated with them (such as age at death). This creates a dilemma that even today the field is attempting to address.[1-4] Supervised ML models (ranging from simple models like decision trees to complex models like neural networks require accurate and informative datasets to train on, and although they might produce high accuracy results, they cannot distinguish between ethical or unethical data.[5] It is therefore our responsibility, as researchers and active practitioners, to encourage reform of how these ML models are created and trained.

One of the most important ways in which a ML model's ethics can be assessed is via the quality and manner of data acquisition. This can refer to training a model using data from populations where informed consent was never obtained or where accurate information is not associated (such as unclaimed bodies). While the benefit to society cannot be minimized, we must find ways in which to honor the dead in a respectful way. These issues can also arise from utilizing large open-source datasets curated for ML use. These datasets may be curated through web scraping, where the internet searches for any information available to be used as data, even if informed consent has not been obtained, or information has been incorrectly labeled.[6] These are the basic ethical concerns that need to be addressed while implementing ML models as decision support tools in forensic anthropology.

The remedies to address these concerns do not require the cessation of research but rather the systemic refinement of datasets as research continues such as the retroactive attainment of authorizations from the families and communities of decedents. The field must also, through training and education, gain a better understanding of what should be considered as an appropriate dataset in both applicability and ethical rigor. Further, while the complete inclusion of informed consent would be the ideal, practically this would be unattainable, as the amount of diversified data required could be lower than the potential pool of persons who ascent to their data's use. Ethical considerations must also factor in the societal benefit in spite of the lack of individual consents.[7] To account for these discrepancies, the field must then begin to develop affirmative, non-perfunctory measures to address the inevitable ethical imbalance as a means of acknowledging the lack of informed consent and recognizing the ethical shortfall. This would bring anthropology back to the basics with a more rigorous ethical foundation as our field moves into an adaptive future.

A170 The Impact of Collection-Specific Sample Bias on Aggregate Cranial Morphology in United States-Based Documented Skeletal Collections

Rhian Dunn, PhD, Western Carolina University, Cullowhee, NC; Joseph T. Hefner, PhD, MSU, East Lansing, MI*

Learning Objectives: After attending this presentation, attendees will be familiarized with a number of biases in United States-based Documented Skeletal Collections (DSCs) with the potential to impact aggregate cranial morphology.

Impact Statement: This presentation will impact the forensic science community by addressing the representativeness and comparability of skeletal data from United States-based DCSs and by discussing the implications for forensic anthropological research.

Abstract Text: DSCs provide some of the samples necessary for forensic anthropological research, including the creation and validation of skeletal analytical methods. Modern DSCs are considered representative of the current living population, but these collections differ by geographic location, organization, and procurement strategies. These factors influence which donors are included in a particular collection *and* create collection-specific sample bias. Identifying how that bias impacts skeletal variation across collections is essential for evaluating the validity of current analytical methods and for employing appropriate mitigation practices in future studies.

This study investigates collection-specific sample bias using demographic and craniometric data from a sample of individuals from eight United States-based DSCs (n = 1161). These include: the John A. William's Documented Human Skeletal Collection, Mann-Labrash Osteological Collection, Maxwell Museum's Documented Skeletal Collection, Michigan State University Forensic Anthropology Laboratory Donated Skeletal Collection, Texas State Donated Skeletal Collection, Southeast Texas Applied Forensic Science Facility Donated Skeletal Collection, Western Michigan University Homer Stryker M.D. School of Medicine Skeletal Teaching and Research Series, and University of Tennessee, Knoxville Donated Skeletal Collection.

To assess collection-specific bias, a series of one-way Multivariate Analysis Of Variance (MANOVAs), two-way MANOVAs, and two-way Multivariate Analysis Of Covariance (MANCOVAs) quantified the impact of collection origin and other demographic variables (e.g., sex, population) on cranial morphology. A Canonical Variate Analysis (CVA) on each MANOVA and MANCOVA aided in visualizing collection separation in multivariate space. Next, Mahalanobis distances (D^2) were calculated to assess similarity/dissimilarity across the various collections and to explore hierarchical relationships. Distance matrices were also calculated between physical collection locations (geographic distance) and the biological distance matrix (Mahalanobis distance) using multidimensional scaling and Procrustes analysis. Two linear discriminant functions assessed whether classification rates were higher when pooling individuals by collection or using traditional biological parameters (population and sex).

Across all MANOVAs and MANCOVAs, collection consistently had a statistically significant impact on cranial morphology ($p < 0.01$), even after accounting for variation from other demographic variables. The CVA revealed the spatial relationship of collections is highly reliant on the demographic variables included in the model, indicating collection origin is not the most influential factor. Evaluation of Mahalanobis distances and geographic distances revealed collection-specific sample bias is not spatially correlated to collection location. Lastly, classification by population and sex outperformed classification by collection origin in the linear discriminant function analysis (overall correct classification rates were 49.0% and 32.0%, respectively).

Overall, collection origin influences the aggregate cranial morphology in modern collections. However, collection-specific sample bias has a smaller influence on the aggregation at each collection than the demographic variables such as sex and population affinity. Samples consistently and preferentially clustered with individuals from similar population and sex groups rather than with individuals from the same collection.

A171 Defining Effective Investigation: A Fundamental Requirement for the Examination of Mass Graves and Other Atrocity Crime Scenes

Ian D. Hanson, PhD, Bournemouth University, Lyndhurst, England, United Kingdom; Melanie D. Klinkner, PhD, Bournemouth University, Poole, Dorset, England, United Kingdom; Diego D. Nunez, MSc, Bournemouth University, Poole, England, United Kingdom; Ellen D. Donovan, MA, Bournemouth University, Poole, England, United Kingdom*

Learning Objectives: Attendees will be provided with definitions of effective investigation, atrocity crimes scenes, and event-led investigation and gain better understanding of international legal (and ethical) obligations with an emphasis on forensic processes. The presentation will demonstrate that to be effective, an investigation process must provide three outcomes utilizing the same evidence, contributing to criminal prosecutions, identification of the missing, and a detailed narrative of events.

Impact Statement: This presentation will impact the forensic community by providing definitions, improved contextualization, and understanding of international forensic investigations, and how their implementation can satisfy diverse requirements under international law.

Abstract Text: Obligations under international law, for example, Article 15 of the International Convention for the Protection of all Persons from Enforced Disappearance, state forensic investigation and identification efforts may form part of an "effective investigation."[1]

Wherever possible, successful investigations will identify victims, repatriate remains to family and communities, and provide an authoritative account of events, including confirmation and certification of death, leading to remedies for families and communities, including rights to compensation; restitution; rehabilitation; satisfaction, and guarantees of non-repetition.[2] Moreover, they should be capable of identifying alleged perpetrators and assist in accountability processes. Under international law an effective investigation is understood as needing to be independent, thorough, impartial, and timely, with a focus on gathering all reasonably available evidence and considering all lines of inquiry, aiding the pursuit of justice. However, there has not been a forensic definition of effective investigation that provides description of what considerations and processes are necessary to fulfil these obligations under international law.

There has been great variation in international investigations and associated outcomes, mapped by the MaGPIE project, and providing a forensic definition progresses the potential of the international community to react to criminal events.[3] Considerations include:

- *An event-led approach to investigations*, based on witness and associated evidence, form the basis of developing prosecutorial and judicial understanding of crimes
- *The scope, nature and connections of atrocity crime scenes* that demonstrates the chronology and serial relationships between sites within a forensic landscape, that connect victims and perpetrators[4,5]
- *Commonality of evidence applications*, that recognizes all evidence classes recovered from atrocity crimes scenes have potential to contribute to criminal evidence, identifying the missing and dating events[2]

Through organizing data gathering in investigations with these concepts in mind, progression of investigations can ensure a number of outcomes:

- Employing suitable forensic applications that lead to recognition and recording of evidence through assessed science-based methods with demonstrable evidential integrity, standardized recording, and integrated interdisciplinary evidence analysis
- Defining process-driven operations that provide a standard range of considerations to ensure the evidence from events is located, recognized, dated, retrieved, examined, analyzed, interpreted, identified, and reported upon
- Providing justified and defensible conclusions that account for loss of evidence and consider alternate interpretation

Given the politicization of international investigations, such an event-led and processual approach provides the potential to:

- Protect mass graves and atrocity crimes scenes through their recognition and defined relation to events
- Promote prevention of further crimes through demonstrable association of events, crimes and perpetrators
- Counter revisionism through describing the fullest account of events, crimes and victims

An effective investigation will provide evidence that will aid successful criminal prosecutions, allow identification of the missing, and advance detailed narrative accounts of related events through implementation of a standardized, integrated, and defined operational process.

A172 Who Are the Nation's Unidentified? Assessing Demographics and Case Characteristics of Long-Term Unidentified Persons in the United States

Molly A. Kaplan, PhD, Operation Identification, San Marcos, TX*

Learning Objectives: After attending this presentation, attendees will better understand trends and significant relationships among the demographics and case characteristics of long-term unidentified persons around the country.

Impact Statement: This presentation impacts the forensic science community by illuminating commonalities and variations among resolved and unresolved long-term unidentified persons cases to inform decedent identification policy and practice.

Introduction: As forensic technologies progress, tens of thousands of individuals continue to go missing each year and remain backlogged as unidentified persons in coroners' and Medical Examiners' (MEs') offices. Despite the human toll on families awaiting answers about lost loved ones, the factors most contributing to this crisis of long-term "cold" cases across the country have yet to be studied. In addition to jurisdictional differences among medicolegal agencies, decedent demographics and case characteristics also seemingly affect case outcomes. Aspects of marginalization have been found to be prevalent among the unknown deceased, such as non-White race, being a non-citizen, and houselessness.[1-3] The completeness and condition of remains, influenced by recovery location and postmortem interval, dictate the preservation of individualizing features and the types of analyses required to confirm positive identification. Assessing patterns of long-term unidentified persons cases is therefore crucial for understanding the solvability of these cases around the country.

The objective of the present study is to assess demographics and case characteristics for both resolved and unresolved long-term unidentified persons cases across the United States.

Methods: Data from a total of 4,139 resolved and unresolved long-term unidentified persons cases were obtained from four medical examiner offices: the Pima County Office of the Medical Examiner in Tucson, AZ, the Harris County Institute of Forensic Sciences in Houston, TX, the New York City Office of the Chief Medical Examiner in New York, NY, and the Wayne County Medical Examiner's Office in Detroit, MI. These offices were selected for their geographic representation and because they serve jurisdictions with high reported rates of missing and unidentified persons.[4]

To analyze trends among these long-term cases, bar plots were generated to examine the frequency distribution of each of the nine variables collected for the resolved and unresolved case samples, as well as across each ME office. To test the statistical relationship between variables and identification status, chi-square tests of independence or Fisher's Exact tests were conducted for each case variable.

Results: The long-term unidentified persons in the present study are predominantly adult males aged 20-59 years. Among long-term cases, persons under 40 years old who are recovered in residences as complete individuals are more likely to be identified, while persons over 40, found in various outdoor locations, with Undetermined manner of death and as partial individuals are more likely to remain unidentified indefinitely.

Discussion: Going "back to basics" by continuing to study patterns in demographics and case characteristics of long-term unidentified persons will help bolster biocultural profiles, improve contextual identifications, and increase the accounting and visibility of the long-term dead. Standardizing data recording for decedent migration status, domicile status, population affinity, and gender identity is crucial for tracking the sociopolitical and public health impacts of various structural vulnerabilities around the country. This will not only serve to better direct resources for long-term cases but will inform the collection of missing persons information to ultimately return more loved ones to their communities.

A173 Digging Up Doe: An In-Depth Study of Exhumations in Cold Case Investigations

Erin H. Kimmerle, PhD, University of South Florida, Institute for Forensic Anthropology and Applied Science (IFAAS), Tampa, FL; Kelsee C. Hentschel-Fey, MA, University of South Florida, Institute for Forensic Anthropology and Applied Science (IFAAS), Tampa, FL; Amanda Schultz, BA, University of South Florida, Institute for Forensic Anthropology and Applied Science (IFAAS), Bushnell, FL; Lauren Nichols, MA, University of South Florida, Institute for Forensic Anthropology and Applied Science (IFAAS), Temple Terrace, FL*

Learning Objectives: The purpose of this presentation is to discuss the common challenges and strategies for the exhumation of buried remains for human identification in cold case investigations. From missing bodies to misaligned graves and the effects of embalming on DNA analysis, best practices for the location, excavation, processing, and analysis John/Jane/Baby Doe graves are explored. The current study is an in-depth review of more than 70 exhumations across three states.

Impact Statement: This is a comprehensive study of the burial practices, embalming methods, varied burial contexts, and the challenges of exhumations through the course of cold case investigations. This presentation has important implications for forensic anthropologists, detectives, coroners, medical examiners, and DNA lab personnel. National efforts to identify America's unidentified human remains are resulting in a significant number of exhumations. This study examines the variation and best practices for exhumation, particularly in terms of how embalming processes and burial environments affect DNA extraction for identification and the recovery of contaminated or lost evidence.

Abstract Text: There are many reasons for exhumations in existing cemeteries, including the identification of an unknown victim, suspect, or offender; DNA collection; trauma analysis; and the reanalysis of an equivocal death. From 2010-2025, the Forensic Anthropology Laboratory at the Florida Institute for Forensic Anthropology and Applied Sciences at the University of South Florida completed 51 grave exhumations of John/Jane/Baby Doe as part of their ongoing cold case programming. This study is a comprehensive review of those cases to determine: (1) the frequency of success in locating and exhuming the body in question, (2) general burial patterns such as the use of embalming or body bags, and (3) the success rate for DNA extraction among buried and/or embalmed cases.

Among the total sample, 51 were successfully exhumed and 21 more exhumations were attempted, but the graves were empty or could not be located due to a loss of records or missing burial information. Among the missing cases, the majority were homicides. Of the cases successfully exhumed, the bodies had been discovered in Florida, Kentucky, or Pennsylvania between 1969-2008. The amount of time that passed between the John/Jane/Baby Doe burial and the exhumation ranged from 7-65 years. Since the primary purpose of exhumation was human identification, elucidating the factors that contribute to the successful extraction of DNA is important. One of the primary goals of this study is to understand the effect that bodies recovered in water or that were immersed in a watery grave for decades or burned have had on DNA extraction. Successful DNA extraction was possible in 38 of the cases, including 22 full DNA profiles, leading to 14 identifications. Nearly all the bodies that were recovered intact, excluding those cases initially found skeletonized, were embalmed. About half of the decedents were buried in a body bag within a wood casket, whereas the rest were in heavier, commercially made caskets, metal caskets, or Styrofoam.

In terms of locating burials, only 15 of the graves had markers. In 7 of these cases, the bodies were located but not in the grave that was listed; rather, they were found in different graves after repeated exhumation attempts. We found numerous incidents where the body recovered in the grave was not the correct individual; the graves may have been misaligned with a headstone or marker; graves were stacked on one another, intruded into one another from the side, and, in some cases, a single casket contained multiple bodies. We also found that the mode of deposition was often inaccurate (e.g., bodies were supposed to be buried but were cremated). The field methods, archival record searches, and intelligence-led strategies used in these cases for locating unmarked burials are discussed. Best practice recommendations are also discussed to help investigators locate burials in their jurisdictions and understand the patterns and trends for which cases are likely to lead to successful DNA extraction.

A174 Operation Identification: Ethnographic Stories Beyond Turning Numbers Into Names

Victoria Soto, MA, Texas State University, San Marcos, TX; Ivanna Robledo, MA, Texas State University, San Marcos, TX; Daniela D. Martinez Herrera, BA, Texas State University, Corinth, TX*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the journeys and stories of the people who we as forensic anthropologists analyze and work on, turning numbers into names. It is imperative that these individuals are seen as that—individuals—and not just remains.

Impact Statement: This presentation will impact the forensic science community by highlighting the importance of family and ethnographic stories that are vital to humanitarian forensic action, reminding the forensic community that in order to have remains to analyze, a person had to lose their life, and we should never lose sight of that. It is easy to get caught up in case numbers, but each person had a name, family, and story as to why they ended up where they did.

Abstract Text: Operation Identification (OpID) is a humanitarian project that works with local, state, federal, international governmental and Non-Governmental agencies (NGOs), and family members to locate, exhume, identify, and repatriate the remains of unidentified individuals found in south Texas. To date, OpID has investigated 692 cases, and of those cases, OpID has identified 225 individuals.

Although 225 people have been identified, a name does not encompass who they were. Only a silent group that has been instrumental in facilitating these identifications can answer that question: the families of the deceased. Families are essential to the investigation and identification of missing and unidentified persons. However, families are often left out of the identification process.

This presentation focuses on four case studies of five individuals who drowned while attempting to cross the Rio Grande River (i.e., Rio Bravo). The family members of these decedents played a vital role in their identification, assisting OpID throughout the process.

Case 1: The National Missing and Unidentified Persons System (NamUs) is an online platform geared to assist in solving missing and unidentified persons cases in the United States. In 2021, Texas Law (2021 TX HB1419), required that all missing and unidentified persons cases are to be uploaded to NamUs. OpID uploaded the case information and photographs of personal effects which ultimately led to an identification.

Case 2: Between 2022-2024, Maverick County became the epicenter of migrant deaths in Texas. In response to the increase in fatalities and lack of storage, the county buried decedents in the county cemetery. In 2022, OpID conducted exhumations to bring the county into compliance with Texas law.

Case 3: In May 2025, OpID traveled to Eagle Pass, TX, and became aware of the case of a 4-year-old who drowned while crossing the border with family. The family of the 4-year-old worked directly with OpID and community members of Eagle Pass to coordinate her funeral. OpID then learned that the young girl's grandmother also went missing during the same incident. In collaboration with Border Vigil, OpID was able to make contact with the mother of the 4-year-old, who then provided missing persons information for comparison with OpID's cases.

Each story is different, and each person has a different reason as to why they decided to make the journey to the United States. Through the identification process, the OpID team was able to learn who these individuals were, not just what their names were. These ethnographic stories are crucial for forensic humanitarian action as they show that to truly be ethical and consider all opinions during the justice process, family members must be included. Additionally, these stories provide evidence that forensic anthropology cannot be performed in a vacuum, and team members with a range of different experiences are needed to perform family-related tasks.

A175 The Missing and Unidentified at La Frontera: Communication Networks and the Forensic Anthropologist's Role at the México-United States Border

Aliya Godoy, MA, Louisiana State University, Baton Rouge, LA*

Learning Objectives: The goal of this presentation is to explore the role of forensic anthropologists in complex networks of communication at the México-United States border in contexts of the missing and unidentified.

Impact Statement: This presentation demonstrates the numerous avenues of communication that forensic anthropologists must navigate in medicolegal efforts at the México-United States border according to collaboration with, and experiences of, forensic professionals. This study highlights how an understanding of these complex communication networks and the possible roles of a forensic anthropologist may contribute to resources for improved cross-cultural and cross-linguistic communication to best address crises like that at the border.

Abstract Text: The Missing Migrants Project reports that in the past 11 years, 11,138 missing migrants have been recorded in the Americas, with 6,512 of those migrants situated at the México-United States border.[1] The crisis of missing and unidentified migrants at the México-United States border is a topic of great discussion in the field of anthropology and specifically in discourses of humanitarian forensic anthropological work. This research addresses the crisis at the border, expanding on the scholarship of family agency and language barriers between Spanish-speaking communities and medicolegal actors by investigating the role of forensic anthropologists in networks of communication at the border. The construction of pathways for information flow is complex and requires consideration of all involved stakeholders, the real and various barriers to communication, and the ways anthropological expertise can be used to navigate these pathways.

Through conversations and collaboration with five forensic anthropologists working along the border, this study focuses on the space occupied by families and medicolegal investigators where communication is pertinent. Through discussion, observation, and collaboration with forensic professionals, this study investigates the impact of *fronteras* (barriers, borders, frontiers) on communication and the role of forensic anthropologists in emotionally charged spaces when searching for missing and unidentified migrants. Forensic anthropologists described the idealized paths of communication when searching for a missing loved one and when attempting to identify a set of remains as well as all the other networks possible in this context. This presentation ultimately addresses the questions: What is the anthropologist's role in the midst of possible communication networks? Where does their work start? Where does their work end? Whose responsibility is it to do this work, to do it well?

Analysis of the interviews conducted and observations made in this study suggest that extensive *fronteras* to communication exist, including language barriers, inequitable access to funding to ensure migrant representation in databases, a need for more time and resources for each step of the investigatory process, intentional miscommunication, and inconsistent data-sharing practices due to decentralization of data and/or unshared centralized data. Alongside migrant communities, these anthropologists navigate such *fronteras* utilizing their expertise and training, forming strategic and holistic relationships, and practicing intentional acts of care.

As forensic anthropologists begin, and continue, to form new communication networks—moving to an international scale—it is important for us to first reflect upon are the current networks in place and the roles anthropologists create and fill. Further, the continually changing context of the border and the crisis (politically, socially, economically, and structurally) calls for an extended examination of how the role of the forensic anthropologist, and the tools they use, might shift, adapt, or remain the same.

A176 Understanding Missingness: A Case Study Utilizing the Mississippi Repository for Missing and Unidentified Persons

Sarajane Smith-Escudero, MA, University of South Florida, Tampa, FL; Rachel Coppock, BA, Mississippi State Unuversity, Starkville, MS; Jesse R. Goliath, PhD, Mississippi State University, Mississippi State, MS*

Learning Objectives: By attending this presentation, attendees will learn the importance of establishing a state-level repository dedicated to missing persons. Additionally, they will have gained a robust understanding of the concept of "missingness" as well as the differential exposure to missingness and adverse case outcomes faced by specific demographic groups.

Impact Statement: This presentation will benefit the forensic science community, specifically forensic anthropology, by furthering theoretical understandings of an under-researched area—missing persons—and conceptualizing missingness through the utilization of social theory in medicolegal case data. The application of social theory to missing persons data highlights empirical patterns previously unexplored, leveraging forensic anthropology's unique disciplinary position to maximize its contributions to the area of missingness. Additionally, this work contributes to current research efforts within the discipline, engaging with social theory in medicolegal investigations.

Abstract Text: The nature of going missing often renders circumstantial information inaccessible to law enforcement, researchers, and the public alike, leaving missing persons and missingness research an understudied area. Recent research has found that across several geographic and jurisdictional contexts, racial and ethnic minorities are typically overrepresented in missing persons data, including in Mississippi.[1-3] Here, we argue that *missingness* is the result of several complex and entwined structural factors that compound upon one another (i.e., structural violence) and necropolitics.[4-7] These structural issues, such as resource allocation, unevenly expose or threaten certain demographics to missingness, which may result in death. Missingness leaves an individual in a state of bare life for an indeterminate amount of time, putting not only their physical and mental health at risk, but also the health of the community from which they are missing.[8] Recognizing *missingness* as an ultimate form of poor health, we advocate for a public health approach, which can consider risk and thus preventative measures.[9,10] Data from the Mississippi Repository for Missing and Unidentified Persons (MS Repository) were used to identify trends of who has gone missing in Mississippi, as well as differences in case resolutions across demographics, to illustrate risk factors of missingness.[11]

The MS Repository is a clearinghouse for missing persons data in Mississippi, serving as a source to gauge demographic, geographic, and temporal trends of missing persons throughout the state. Over 2,300 missing persons cases have been systematically input into the MS Repository since 2022, spanning reported cases from the 1950s to present day, with numbers and resolutions fluctuating daily. In the current project, data were collected from the MS Repository on all missing persons cases, their demographics, case resolutions, and information regarding manner of death for those who were unfortunately recovered deceased. As of June 2025, 2,339 persons were reported missing in Mississippi. A total of 2,313 missing persons cases with complete demographic data and recorded case resolutions were analyzed. Significant disparities between case outcomes exist across demographic groups, with Black, Indigenous, and People Of Color (BIPOC) individuals overrepresented in missing persons reports regardless of case resolution (59%). However, they only make up about 30% of the population of Mississippi.[12] Of the 2,313 reported missing persons cases, 50.02% (n=1,158) were recovered alive, 39.65% (n=918) remain missing or unresolved, and 10.24% (n=237) were found deceased. Differences in manner of death for those found deceased are a cause for concern; missing Black males who are found deceased are more likely to have died a homicidal death in comparison to their female or White counterparts.

Differential exposure to (and constant threat of) not only missingness but resultant violent death can be conceptualized as the consequences of structural violence and necropolitics. Future research in this area would benefit from comparisons of missing persons demographic trends across states and regions. This research aims to contribute to the disciplinary movement of incorporating social theory within forensic anthropology by furthering theoretical conceptualizations of *missingness* while parsing apart concerning trends in missing persons case resolutions in Mississippi.[13-15]

A177 A Preliminary Review of Long-Term Unidentified Decedents at the West Tennessee Regional Forensic Center

Lauren K. Santoro, BS, Baptist Health Sciences University College of Osteopathic Medicine, Memphis, TN; Danielle K. Harrell, DO, University of Tennessee Health Science Center- West Tennessee Regional Forensic Center, Memphis, TN; Diana Messer, PhD, West Tennessee Regional Forensic Center, Memphis, TN*

Learning Objectives: Attendees will learn how to initiate and structure a comprehensive inventory of long-term unidentified cases, including strategies for data collection, case assessment, and investigative triage. This presentation will outline key steps in identifying investigative gaps and prioritizing next actions. Additionally, attendees will gain insight into the demographic, pathological, and anthropological patterns observed among long-term unidentified individuals at the West Tennessee Regional Forensic Center (WTRFC).

Impact Statement: This presentation will impact the forensic science community by providing a practical framework for initiating a systematic review of long-term unidentified persons, highlighting the value of such inventories in identifying investigative needs, improving case management, and advancing identification efforts through interdisciplinary collaboration and database integration.

Abstract Text: As of May 2025, there are a reported 25,628 unresolved missing persons and 15,363 unidentified persons in the United States.[1] Western Tennessee is significantly impacted by the missing and unidentified persons crisis, with Memphis ranked fifth in the nation for the highest number of open missing persons cases.[2] This study aimed to compile and assess the extent of long-term unidentified persons cases managed at the WTRFC, examine decedent patterns and characteristics, and evaluate next steps in the investigative and identification process.

A retrospective review of long-term unidentified decedent cases from 1981 to 2024 was conducted at the WTRFC. Cases were identified through multiple sources, including records compiled by previous staff, the presence of physical remains, and entries in the National Missing and Unidentified Persons System (NamUs). A comprehensive review of all available postmortem documentation was performed, including autopsy reports, law enforcement records, as well as anthropological and dental examinations. Data collection focused on decedent demographics, scene context, autopsy findings, laboratory testing, need for updated analyses, and national database case entry status.

A total of 51 long-term unidentified decedent cases were identified, with the majority (78%) originating from Shelby County (n=40). Outdoor recovery locations accounted for 72% of cases (n=37), most commonly involving wooded, rural, or abandoned urban areas. Most individuals were discovered in an advanced state of decomposition (67%; n=34), limiting traditional identification methods. Fingerprints were obtained from 11% of individuals (n=6). Dentition was present in over half of the cases (67%, n=34), and 20 cases have had a forensic odontology consult (39%). The manner of death was most frequently classified as Undetermined (41%, n=21); however, 6 cases were identified as Homicides and 4 as Accidents. For more than half of the cases dated prior to 2006, official records could not be located from the county archives. To date, only 22 cases have been submitted for DNA testing and entry into the Combined DNA Index System (CODIS), with 8 cases sent for Forensic Genetic Genealogy. Preliminary anthropological assessments were conducted in 49% of cases (n=25), and 29 require updated anthropological analysis. Several cases were found to have actionable leads (e.g., a known last name) that warrant renewed investigative efforts. While 70% of cases have been entered into NamUs (n=36), only 9 have been entered into the National Crime Information Center (NCIC), underscoring the need for stronger interagency collaboration. A lack of direct NCIC access and a dedicated unidentified persons manager at the WTRFC have limited long-term investigative follow-up and data sharing with law enforcement.

Next steps include prioritizing cases with viable biological samples for DNA testing and completing updated anthropological analyses where warranted. Efforts should focus on locating or reconstructing missing records, enhancing interagency collaboration, and ensuring all eligible cases are entered into the appropriate databases
(e.g., NamUs, NCIC) to maximize identification potential. Establishing a formal cold case task force and standardized protocols for documentation, review, and database entry will be critical to improving outcomes for long-term unidentified decedents in the region.

A178 A Look at the Disaster Response to Hurricane Katrina: How Far Have We Come in 20 Years?

Gina O. Hart, MA, Jefferson Parish Coroner's Office, Harvey, LA; Julia Powers, MA, Jefferson Parish Coroner's Office, Harvey, LA; Ryan M. Siedemann, PhD, University of New Orleans, Prairieville, LA*

Learning Objectives: This presentation will provide attendees with the background of Hurricane Katrina and the response of the forensic community afterword. Attendees will learn what was done, the evolution of disaster response today as it relates to Hurricane Katrina, and improvements and changes made in the wake of this seminal disaster in American history.

Impact Statement: This presentation will impact the forensic science community by reviewing past responses to natural disasters as they pertain to Hurricane Katrina, how those responses have changed in the past 20 years, and what forensic scientists can continue to do to improve the analysis, identification, and redistribution of remains in mass disaster events.

Abstract Text: On August 29, 2005, Hurricane Katrina made landfall in Louisiana as a category 3 storm. A failure of the levee system in New Orleans led to flooding of 80% of the city. Significant damage from winds and flooding destroyed areas surrounding New Orleans, in both Louisiana and Mississippi. Approximately 1,836 deaths across several states can be attributed to Hurricane Katrina. In addition, an unknown number of dead were forcibly ejected from their burial places across the Mississippi Delta's crow's foot. The Katrina dead and how they were managed were often overshadowed by the thousands of living people displaced from the area because of the widespread damage. The destruction to local resources caused significant hurdles to recovery, identification, and redistribution of remains after the storm. The Disaster Mortuary Operational Response Teams (DMORT) established its biggest and most ambitious response at that time with two morgue locations in Louisiana and Mississippi and a long-term operation in Louisiana.

In the shadow of the 20th Anniversary of Hurricane Katrina while AAFS is meeting in the epicenter of the storm's devastation—New Orleans—this presentation provides a retrospective of the anthropological response to Hurricane Katrina. The presentation also tells the postmortem narrative of Katrina's unclaimed and unidentified dead, the failure due to bureaucratic and legal limitations of some postmortem recovery efforts, the diminished role of DMORT in aspects of Louisiana's management of certain disaster impacts, and Louisiana's pioneering approach to protecting against some of the failures of Hurricane Katrina. This legacy of Hurricane Katrina is situated within the response work occurring following Hurricanes Ike and Gustav (2008), Isaac (2012), Louisiana's Great Flood of 2016, and Hurricanes Laura, Delta, and Zeta (2020), and Ida (2021).

A179 When Men Are Prey: Melee Skeletal Trauma Patterns From the 1921 Tulsa Graves Investigation

Phoebe R. Stubblefield, PhD, PhD, CA Pound Human Identification Laboratory, University of Florida, Gainesville, FL; Angela K. Berg, MA, Oklahoma OCME, Tulsa, OK; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University, Fort Myers, FL; Arion T. Mayes, PhD, San Diego State University, San Diego, CA; Sheridan Lea, MSc, University of Florida, Gainesville, FL*

Learning Objectives: After attending this presentation, attendees will be able to summarize the trauma to victims recovered in the City of Tulsa 1921 Graves investigation and describe a trauma pattern associated with mob violence.

Impact Statement: This presentation contributes to riot-related trauma analysis that focuses on the injury patterns to multiple victims of mob activity in the United States, rather than trauma associated with controlling mob behavior.

Abstract Text: Since 2020, the City of Tulsa has engaged in field recovery for victims of the 1921 Tulsa Race Massacre. We describe the ballistic perimortem trauma observed amongsthe 47 exhumed burials to date, and relate, if applicable, their injuries to the historical narrative of those killed in the race massacre.

The historical accounts of the Tulsa Race Massacre document that after a gunbattle on the night of May 31, 1921, a White Tulsan mob entered the unincorporated neighborhood of Greenwood on June 1, 1921, and systematically looted and burned 39 blocks of residences and businesses.[1,2] The narrative chronicles how the Greenwood residents engaged with and fled from armed combatants. From this event, death records exist for 39 Black and White men and 1 Black woman; 20 Black males both identified and unidentified were buried in unmarked graves in Section 20 of Oaklawn, the city cemetery of Tulsa. Since most of these 20 individuals had Gunshot Shot Wounds (GSW) recorded on their death certificates, we sought to exhume and identify males with GSW trauma during our investigation of the cemetery.

Since the 2021 field season, we investigated three regions of Section 20, including the "Original 18" and the "Clyde Eddy" areas, the former containing the majority of GSW victims. A total of six definite GSW victims and one possible have been recovered. The possible individual was recovered with an isolated scatter of radiopaque particles, but no other indicators of GSW such as entrance/exit wounds, fractures, or presence of a bullet. Of the remaining six, one had a single cranial GSW, while the other five had multiple GSWs. Three individuals had ballistic material recovered from anatomical areas that suggest a target preference. Two of the multiple GSW victims, one which was also burned, had retained projectiles from multiple ballistic weapon types, which suggests multiple assailants.[3] Two of the victims also exhibited ballistic trauma to the lower limbs, which suggested strategic use of weapons to immobilize the victims.

A wealth of literature exists for patterns of mob violence internationally, although similar literature for well-known events in the United States is sparser.[4-9] In comparison, death by GSW is much more prevalent in the Tulsa event than in modern international literature. However, the patterns of injury here could suggest attempts at delayed death as a form of torture.[10] Our results present an initial pattern of historic American mob violence that we hope to expand upon in future field work.

A180 A Preliminary Examination of the Evidentiary Value of Trauma to Individual Skeletal Elements in Distinguishing Between Circumstances of Death

Maria Nektaria Antoniou, LLM, MSt, University of Oxford, Oxford, England, United Kingdom; Nicholas Marquez-Grant, PhD, Cranfield University, Oxford, England, United Kingdom; Rick Schulting, PhD, University of Oxford, Oxford, England, United Kingdom*

Learning Objectives: Through the juxtaposition of perimortem-trauma data from 20th-century battlefield deaths and extrajudicial executions, attendees will become familiar with the evidentiary value that trauma to individual skeletal elements can have in distinguishing between lawful from unlawful circumstances of conflict-related death.

Impact Statement: This presentation addresses the weight that isolated elements devoid of context could carry in the determination of the legality of circumstances of death in conflict as a preliminary test of their evidentiary value in war-crime prosecutions. As a result, practitioners called on to examine partial remains in the context of conflict, where commingling is common, will have empirical support for making probabilistic suggestions on what could reliably be inferred from trauma about circumstances of death.

Abstract Text: A common defense put forth in war-crime prosecutions is that the deaths in question occurred in combat rather than as a result of execution, which makes the ability to distinguish between these two circumstances of death particularly salient for legal proceedings.[1] The expectation that executions will exhibit different trauma patterns than battlefield deaths has rarely been empirically investigated, and the few comparative assessments usually exclude incomplete sets of remains from consideration and include data from battlefield injuries that were survived.[2-4] There is consequently little to no guidance on the weight that perimortem trauma to isolated skeletal elements can carry in judicial proceedings where the defendant claims that the deceased died in combat.

This presentation seeks to revisit the proposition that trauma patterns will differ between executions and combat deaths and explore its validity using parameters that reflect the commingled condition in which remains are frequently found in conflict.[5,6] It therefore tests the hypothesis that the frequency of trauma to individual skeletal elements differs between them as an initial step toward eventually determining the weight of various combinations of trauma locations in clarifying the lawfulness or lack thereof of a conflict-related killing.

A preliminary sample of 100 sets of remains of varying degrees of completeness was drawn from autopsy reports admitted as exhibits before the International Criminal Tribunal for the former Yugoslavia as well as publications detailing trauma on individual skeletons from various 20th-century conflicts. Individuals were chosen on the basis of how precisely the information about trauma locations was reported. The sample is split equally between battlefield deaths and extrajudicial executions, represents a wide geographical range, and spans the entirety of the 20th century.

Chi-squared tests were used to determine whether the frequency of perimortem fractures to the frontal, parietals, occipital, os coxae, humeri, and femora as recorded in this sample differed between lawful and unlawful killings. Despite the expectation that skull trauma would be more prevalent in executions and appendicular trauma more common in combat deaths, this small sample shows no statistical difference ($\alpha = 0.05$) in the frequencies of trauma to individual elements between lawful and unlawful killings with the exception of trauma to the occipital bone, which shows significantly higher prevalence in the execution sample. The femur was also chosen for an initial assessment of whether recording trauma locations more precisely on single elements using the zonation method yields significant differences between the two circumstances of death.[7] Fisher's exact tests did not show significant differences in the frequencies of trauma to individual zones of the femur.

This preliminary assessment suggests that, when isolated, single elements are unlikely to be sufficiently indicative of the circumstances of death when addressing the distinction between executions and battlefield deaths for use in judicial proceedings. Larger samples may provide different results, but reporting perimortem trauma patterns more comprehensively (rather than focusing on trauma that is likely to have caused death) is more likely to yield data that allow for distinctions between circumstances of death to become perceptible.

A181 Necrosilences of the Central Mediterranean: A Preliminary Exploration of Differential Treatment Within the Medicolegal Systems of Tunisia & Malta in Their Responses to Missing and Deceased Migrant Cases

Skylar Joseph, MS, Leiden University, Amsterdam, Noord-Holland, Netherlands*

Learning Objectives: After attending this presentation, participants will understand how the medicolegal systems in Tunisia and Malta process missing and deceased migrant cases, how these investigative processes fall short, and how broader legal and political frameworks undermine an effective search process.

Impact Statement: This presentation will impact the forensic science community through highlighting systemic inadequacies present in the existing search processes for missing and deceased migrants, where Tunisia and Malta serve as case studies toward understanding similar patterns in other contexts around the Mediterranean sea routes.

Abstract Text: When migrants go missing or die attempting to cross the Mediterranean Sea, their families have the right to know their fate and whereabouts. However, this right is routinely denied due to systemic failures within the existing Medicolegal Systems (MLS). These failures stem less from a lack of properly trained forensic professionals and more from systemic underfunding, policy neglect, and legal ambiguity, particularly when the deceased are undocumented, racialized, or politically marginalized.

Through this preliminary assessment and multidisciplinary approach to analysis, the medicolegal systems in Tunisia and Malta are assessed through a critical lens, focusing primarily on the processes for investigating missing and deceased migrant cases. Although the two countries differ in resources, infrastructure, and guiding procedural policies, both exhibit similar failures such as: the underreporting of migrant deaths and disappearances, minimal identification efforts attempted for suspected migrants, poor family tracing mechanisms, and legal frameworks ill-suited to transnational cases. Furthermore, these contexts each demonstrate how discriminatory practices, policies, and political disinterest result in widespread *necrosilences*: the silencing or erasure of certain deaths through state policy or inaction.[1] These silences are reflected in missing data, weak investigative follow-through, and the growing phenomenon of "ghost shipwrecks," where deaths are neither recorded nor investigated.[2]

Present research on this topic tends to be siloed in its approach, whereas the present research seeks to span disciplinary divides to more comprehensively analyze the deeper and cross-disciplinary flaws within the existing system. Through a detailed literature review and assessment of data collected from a variety of different actors involved in the search for missing and deceased migrants in Tunisia and Malta, this study focuses on consolidating this disperse data in order to analyze the contexts of Tunisia and Malta more fully. By better understanding how these medicolegal systems function in response to missing and deceased migrant cases, initial recommendations can be made for improvement. While the present research is still preliminary, it serves as a base for future research to build upon and for policy makers to consider when attempting to improve their search processes for missing and deceased migrants.

States need to be held accountable when they do not properly investigate missing and unidentified persons cases properly. Additionally, recent migration control agreements between European and North African states have contributed to heightened risks at sea while offering little support for rescue, recovery, postmortem identification, or family engagement. The forensic invisibility of many migrants is not merely an oversight, it is a strategic omission enabled by racialized politics, jurisdictional complexities, and a vast deprioritization of medicolegal systems and forensic services at a baseline.

Using Tunisia and Malta as illustrative case studies, this research demonstrates how politicized neglect undermines MLS capacities and impedes the realization of truth, justice, and dignity for migrant decedents and their families. By unpacking the structures that enable necrosilences, this research advocates for the development of more equitable search procedures, more rights-based MLS protocols, and a prioritization of medicolegal systems and forensic services, especially for regions affected by mass migration disasters.

A183 The Forensic Identification of Semi-Skeletonized Remains in Ukraine: A Case Study

Laura Donato, University of Tor Vergata, Laboratory of Anthropology and Forensic Aging, Section of Legal Medicine, Social Security and Forensic Toxicology, University of Tor Vergata. Volunteer Military Corps of the Italian Red Cross., Rome, Lazio, Italy; Marta Garazdiuk, MD, Bukovnian State Medical University, Chernivtsi, Chernihivs'ka Oblast', Ukraine; Douglas H. Ubelaker, PhD, Smithsonian Institution, Washington, DC, Michele Treglia, MD, Department of Biomedicine and Prevention, University of Rome, Laboratory of Anthropology and Forensic Aging, Section of Legal Medicine, Social Security and Forensic Toxicology, University of Tor Vergata, Rome, Lazio, Italy; Luigi Tonino Marsella, MD, Department of Biomedicine and Prevention, University of Rome, Laboratory of Anthropology and Forensic Aging, Section of Legal Medicine, Social Security and Forensic Toxicology, University of Tor Vergata., Rome, Lazio, Italy; Mahmoud Mohammed Zalat, PhD, Geophysics Department, Cairo, Al Qahirah, Egypt*

Learning Objectives: From this presentation, attendees will learn about the identification activities carried out to study unidentified victims in a war context. Forensic activities will be described as an example of the practical application of scientific knowledge in a critical context.

Impact Statement: This presentation will impact the forensic science community in terms of competence/ability in managing forensic activities in emergencies and high-risk contexts. Furthermore, performance will be described in terms of prioritizing the selection of activities to be carried out. The presentation shows how forensic activities were selected based on the constraints imposed by the war context to still achieve a successful outcome.

Abstract Text: Conflict-related deaths pose a challenge for forensic science. Managing identification procedures in a context such as wartime carries the risk of insufficient facilities and personnel and limited time. Forensic sciences are playing a fundamental role in supporting the identification of victims of the current conflict plaguing Ukraine. Forensic scientists are working to handle the ongoing emergency with the resources at their disposal. As an example of investigative practice, the authors present a case study.

The case involved a semi-skeletonized male corpse recovered from a conflict zone in Ukraine, delivered to the Forensic Bureau. External examination revealed advanced decomposition and a gunshot wound to the right temporal region showing radiating fractures and 1.1 cm diameter entry. The analysis of the cranial wound features aligned with circumstantial evidence. The study of the trauma confirmed a fatal penetrating head injury with brain destruction, consistent with perimortem trauma.

Key identification markers included critical findings such as dental records, metal-ceramic bridges, and unique dental work matched with antemortem data. Moreover, clothing features were examined. Tactical gear inscribed with "Z.A.V." and boot tags matched the victim's name. The advanced state of decomposition prevented the recognition of facial features. However, identification was possible thanks to DNA analysis applied to a femoral shaft and teeth samples.

This case highlights the centrality of multidisciplinary methods. Forensic odontology, anthropology, and genetics were employed for identifying decomposed remains while adhering to forensic ethics. A critical role is played by meticulous documentation and the practitioner's role in bridging science and justice.

A184 Reducing Identification Timelines in South Texas: Assessing the Impact of Postmortem Fingerprinting on Medicolegal Bottlenecks

Mackenzie Murray, BS, Operation Identification, Austin, TX; Molly A. Kaplan, PhD, Operation Identification, San Marcos, TX; Kate Spradley, PhD, Forensic Anthropology Center at Texas State University, San Marcos, TX; Courtney C. Siegert, PhD, Operation Identification, San Marcos, TX; Victoria Swenson, PhD, Operation Identification, San Marcos, TX; Valerie C. Arroyo, BA, Operation Identification, Houston, TX*

Learning Objectives: After attending this presentation, attendees will better understand how the implementation of postmortem fingerprinting protocols improves efficiency of identifications facilitated by Operation Identification (OpID) at Texas State University. They will gain insight into how bureaucratic processes and bottlenecks caused by the fragmented Justices of the Peace (JP) medicolegal system in Texas affects case progression.

Impact Statement: This presentation will impact the forensic science community by demonstrating how the integration of postmortem fingerprinting and standardized Disaster Victim Identification (DVI) protocols can improve identification timelines despite systemic challenges. It will also underscore the need for centralized data systems, stronger inter-agency collaboration, and policy enforcement to reduce case delays caused by the medicolegal system in Texas.

Introduction: Texas death investigations are county dependent, with most cases being investigated by elected Justices of the Peace (JP) who are overwhelmed by disproportionate caseloads, insufficient resources, and limited training. While there are challenges to every step of the identification process, from decedent recovery to obtaining antemortem information, particularly DNA, bottlenecks in case resolution are also deeply bureaucratic. Once a fingerprint or genetic match is obtained, an identification is not official until the JP, the jurisdictional authority, reviews the identification report and signs a petition form, a process that can cause major delays. Once a signature is obtained, coordinating transnational repatriation is complex, costly, and time-consuming, further hindering the swift return of decedents to their loved ones.

OpID was founded in 2013 to facilitate positive identification and repatriation of unidentified human remains found along the Texas-Mexico border. Originally founded to assist with the exhumation of long-term cases, OpID has recently implemented a DVI protocol to aid in the management of ongoing deaths and build medicolegal capacity in the region. In the past two years, OpID has incorporated postmortem fingerprinting into identification efforts. To date, OpID has assisted with 693 cases, 517 of which were received prior to implementing DVI protocol and 176 of which have been received after. Currently, OpID has facilitated a total of 233 positive identifications.

Objective and Methods: The objective of this presentation is to evaluate whether the implementation of DVI protocols, particularly postmortem fingerprinting, has affected the length of time from decedent recovery to identification. Case timeliness was calculated for all identifications and compared from before (n=176) and after the incorporation of DVI protocols (n=66). Timelines were calculated in average days, months, and years from the date recovered, date of positive identification (through circumstantial identification, genetic association, or fingerprint match), and the date the JP signature was obtained.

Results: Pre-DVI identification times from recovery to identification results were a little over three years. Afterward, the average time decreased to a little over one year. The average time between decedent recovery to obtaining the JP signature for all 233 cases is approximately 2.5 years, with a range of a few hours to a little over 19 years. The average time between decedent recovery to the JP signature prior to implementing DVI protocols is 3.5 years, whereas recovery time to JP signature post-DVI implementation is 1.5 years.

Discussion: While OpID's development of DVI protocol and implementation of fingerprinting has seemingly increased the swiftness of identifications, logistical obstacles in certifying the decedent's identification remain. Several case studies will be presented to highlight delays in confirming identifications.

Conclusions: Identifying unknown decedents in Texas requires centralized postmortem data and extensive coordination among numerous local, state, federal, and international agencies. Improving data sharing and collaboration among local authorities, medicolegal institutions, and international stakeholders could accelerate death investigations and reduce this timeline. Achieving these collaborations, however, depends on the implementation of clear policies, adequate funding, and educational outreach to ensure compliance with state laws.

B1 Advancing Forensic Analysis With Chemical Imaging Microspectroscopy

James Cizdziel, PhD, University of Mississippi, Annapolis, MS; Kendall Wontor, PhD, University of Mississippi, Annapolis, MS*

Learning Objectives: This presentation will help attendees: (1) understand chemical imaging microspectroscopy by explaining how chemical imaging microspectroscopy integrates microscopy and spectroscopy to map the spatial distribution of chemical components in forensic samples, using techniques like micro-Fourier Transform Infrared (μ-FTIR) and Optical Photothermal Infrared (O-PTIR) to obtain spectral signatures; (2) analyze automotive paint Layers by comparing the use of μ-FTIR and O-PTIR for chemically characterizing automotive paint chip cross-sections, understanding the advantages of transmission and transflection modes in μ-FTIR, and the role of complementary Raman spectra in O-PTIR for identifying compounds like titanium dioxide; (3) evaluate fingermark analysis techniques by describing the challenges and best practices for transferring and analyzing latent fingermarks using chemical imaging microspectroscopy; (4) apply microspectroscopy to ink analysis by demonstrating the application of micro-Attenuated Total Reflection/FTIR spectroscopy (μ-ATR-FTIR) for analyzing ink on documents; and (5) assess non-destructive forensic methods by evaluating the benefits of non-destructive microspectroscopy techniques (e.g., μ-FTIR, O-PTIR, μ-ATR/FTIR) for forensic applications, focusing on their minimal sample preparation, high spatial resolution, and potential for integration into forensic workflows to enhance evidence analysis.

Impact Statement: This presentation on chemical imaging microspectroscopy will showcase advanced, non-destructive analytical techniques that enhance the analysis of critical evidence types, such as automotive paint chips, fingermarks, and document inks. By demonstrating the superior capabilities of μ-FTIR and O-PTIR for characterizing a range of samples, the presentation introduces a streamlined, high-resolution approach that improves accuracy and sample throughput. The insights into fingermark analysis address key challenges in latent print examination, offering practical solutions to maintain chemical integrity. Furthermore, the application of μ-ATR/FTIR for ink analysis provides a robust method for document analysis with minimal sample preparation. These non-destructive techniques, with their potential for integration into forensic workflows, will empower forensic scientists to achieve more reliable results, reduce evidence degradation, and advance the pursuit of justice. By highlighting state-of-the-art methods and their practical implications, this presentation will inspire adoption, foster interdisciplinary collaboration, and drive innovation in forensic evidence analysis.

Abstract Text: Chemical imaging microspectroscopy are advanced analytical techniques that combine microscopy with spectroscopy to obtain spatially resolved chemical information from a sample. They enable the visualization and chemical characterization of materials at a microscopic level by mapping the distribution of chemical components based on their spectral signatures. Here, we highlight key microspectroscopy techniques and provide three examples of how they are advancing chemical analysis of forensically relevant samples, including characterizing the layers of paint in automotive paint chips, the composition and distribution of chemicals in fingermarks, and the differentiation of ink on documents.

For automotive paint, we evaluated both μ-FTIR and O-PTIR to chemically image cross sections of paint chips without manually separating the layers. For μ-FTIR, transmission and transflection modes provided the highest quality spectra compared to reflection and μ-ATR analyses. Point analysis was preferable to chemical imaging, as peaks were identified in the point (MCT) detector's lower spectral range that was below the imaging (FPA) detector's cutoff, such as those associated with titanium dioxide. Reduced spectral range can lead to a similar issue in O-PTIR analyses depending on instrument configuration. However, its complementary Raman spectra showed strong titanium dioxide peaks, providing an alternate means of identification. Both techniques are likely to become more relevant as they are non-destructive and avoid manual separation of the layers. O-PTIR is particularly well-suited for analysis of the thin primer layer due to its superior spatial resolution. For fingermarks, we will highlight the state-of-the-art and discuss the challenges of transferring fingermarks to materials amenable for chemical imaging analyses. For fingermarks on glass slides, we observed that storage in a dessicator best preserved the chemical compounds within the latent fingerprint. For ink analysis, micro-attenuated total reflection FTIR spectroscopy (μ-ATR-FTIR) provided the best spectra from documents. Overall, microspectroscopy is non-destructive, requires minimal sample preparation, and has the potential to be integrated into forensic workflows to advance forensic science for the pursuit of justice.

B2 An Expanded Uncertainty Assessment of GC/MS Chromatographic Peak Area and Retention Time

Emma Hardwick, BA, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about the different sources of uncertainty and their magnitudes of contribution toward the overall uncertainty of Gas Chromatography/Mass Spectrometry (GC/MS) peak area and retention time measurements. The audience will learn about the effect of concentration, instrument, elution order, and usage on peak area and retention time measurements as well as the impact of using an internal standard to mitigate uncertainty. This information will provide attendees with greater knowledge about the typical uncertainty associated with GC/MS peak area and retention time measurements and help laboratories assess typical uncertainties for their peak area and retention time measurements.

Impact Statement: This presentation will impact the forensic science community by providing an understanding of the typical uncertainty associated with GC/MS peak area and retention time measurements. Identifying common factors and the associated magnitude of their contribution to the corresponding measurement uncertainty will help identify which factors must be controlled to minimize peak area and retention time variability. Providing an objective assessment of the importance of an internal standard to minimize measurement uncertainty as well as the typical variability associated with GC/MS peak area and retention time measurements are important contributions of this work.

Abstract Text: GC/MS is the gold standard technique for seized drug analysis, but also commonly employed for toxicology and trace evidence casework. As with any analytical technique, there is uncertainty associated with GC/MS measurements. However, assessment of measurement uncertainty can be challenging for forensic laboratories. Currently, many organizations provide acceptance criteria for retention time uncertainty; however, there has been little research into the uncertainty associated with GC/MS peak area. This longitudinal study examines four potential sources of uncertainty and assesses their impact on peak area, relative peak area, retention time, and relative retention time measurements. The central hypothesis of this research is that each factor (i.e., concentration, instrument, elution order, and usage) will have a different impact on each variable (i.e., peak area, relative peak area, retention time, and relative retention time) and that understanding this impact will help inform the community about the typical uncertainty for GC/MS measurements.

Three Agilent GC/MS instruments were utilized for this study. A low and high concentration mixture of 16 commonly encountered seized drugs or metabolites was created, and the same method was optimized for all three instruments. The mixtures were analyzed twice a week for five months, with five replicates collected each day. The ChemStation integrator was used to extract the peak areas and retention times. Expanded Uncertainty (U) was calculated using 2*(%RSD), estimating a 95% confidence interval. A combined expanded uncertainty (U_c), based on a weighted average, was chosen to report within-day, within-week, and within-month uncertainties. A one-way Analysis of Variance (ANOVA) was performed to assess the impact of instrument (2021, 2014, 2009), elution order (early, middle, late), and usage (month-to-month variability) on peak area and retention time measurements. Due to only two levels of concentration (i.e., high and low), an independent samples t-test was used to assess the impact of concentration. Effect sizes were estimated using eta squared η^2.

The U_c for peak area measurements was larger than for retention times. For relative peak area measurements, the U_c was smaller than for peak area measurements. In comparison, the U_c was similar for retention time and relative retention time measurements. The general range of U_c for peak area measurements was 20-56%, whereas the range of U_c for relative peak area measurements was only 13-27%. All four factors had a significant impact ($p < 0.001$) at the 95% confidence level (i.e., $\alpha = 0.05$) on the peak area and relative peak area measurements. The η^2 assessment revealed that elution order had the largest impact on peak area variability, at 20.5%, followed by concentration at 14.5%, instrument at 6.8%, and usage at 4.2%. The low concentration U_c was higher than the high concentration U_c for peak area and relative peak area measurements. Retention time and relative retention time had smaller U_c ranges from 0.03-0.10% and 0.03-0.08%, respectively. Only elution order had a significant impact ($p < 0.001$) at the 95% confidence level (i.e., $\alpha = 0.05$) on retention time and relative retention time measurements, with an η^2 value of approximately 83% for both retention time and relative retention time.

B3 The Application of HS/SPME-GC/MS for Hydraulic Fluid Compound Detection in Jet Fuels

Javier E. Hodges, BS, Sam Houston State University, Huntsville, TX; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: The attendees will learn an effective analytical method to detect the presence of hydraulic fluid contaminants in jet fuel using Headspace/Solid-Phase Microextraction Coupled to Gas Chromatograph/Mass Spectrometer (HS/SPME-GC/MS). The technique demonstrates the ability of HS/SPME-GC/MS to analyze and distinguish components of volatile organic compound mixtures.

Impact Statement: GC/MS provides great discrimination power for chemical evidence and is a staple in forensic laboratories. In some cases, the GC/MS technique in this work can be applied for sample classification and quality control. The forensic science community will benefit from this presentation by becoming aware of the development of using HS/SPME sampling to profile volatile chemical attributes of evidence.

Abstract Text: HS/SPME-GC is a modification of traditional GC. Rather than injecting a liquid aliquot of a sample into the inlet column, HS/SPME-GC extracts volatile components from the headspace of a sealed vial containing the evidence. The main advantage of HS/SPME-GC is that it exclusively transports volatile components of the sample through the column, which is ideal for GC analysis. When this chromatographic technique is paired with MS, as most forensic GC methods are, the analyst has access to a plethora of chemical information. In this work, we used HS/SPME-GC/MS to analyze jet fuel samples contaminated with hydraulic fluids.

Hydraulic fluids are hydrocarbon fluid products used in engine-powered vehicles to transfer energy through transmission systems, provide lubrication, regulate temperatures, and seal internal systems. These materials can be made using petroleum-based or synthetic-based manufacturing processes. While petroleum-based hydrocarbon fluids are refined directly from crude oil distillates, synthetic-based hydrocarbon fluids are manufactured by organic synthesis, enabling these products to achieve their respective purposes more effectively. The major subclasses of synthetic-based hydrocarbon fluids include polyalphaolefin (PAO)-based, polyol ester-based, and phosphate ester-based hydrocarbon fluids, among others. Inter-product variations exist between and within these subclasses due to industrial additives that aim to improve traits, including thermal stability, solubility, and fire resistance. It can be challenging to develop a method capable of detecting contaminants with variable components. Nevertheless, this research work demonstrates that the HS/SPME-GC/MS method can detect a variety of hydraulic fluid contaminants in jet fuels.

A total of 150 unique samples were made from five types of jet fuel, six contaminants, and five contamination levels. Two of the hydraulic fluids were petroleum-based, and the remaining four were different synthetic-based products. Aliquots of each sample, 5 µL, were placed in 20 mL headspace sampling vials. An Agilent GC/MS system with an autosampler was used to collect data. The method run-time was approximately 20 minutes.

Analysis of the GC/MS data revealed that synthetic-based hydraulic fluids are more readily detected in jet fuel mixtures. One petroleum-based hydraulic fluid was undetectable in the Total Ion Chromatogram (TIC), prompting the use of Selected Ion Monitoring (SIM), which proved to be a useful tool for detecting all hydraulic fluid contaminants and lowering their limit of detection.

Detecting jet fuel contaminants is a crucial task for forensic scientists working in aviation settings. A reliable method of flagging unsafe fuel can ultimately save money on engine maintenance and other related repairs, and more importantly, it keeps aircraft personnel and passengers safer. Going forward, the research group envisions expanding this analysis to capture more diverse jet fuel contaminants, including other hydrocarbon fluids, sustainable aviation fuel additives, and even hydrophilic chemical species.

B4 An Evidence-Based Method for Determining Cause of Death in a Double Homicide Involving Matricide and Patricide

Gennaro Baldino, MD, PhD, Messina University, Messina, Sicilia, Italy; Cataldo Raffino, MD, INAIL, Enna, Sicilia, Italy; Giorgia Burrascano, MD*, Messina University, Messina, Sicilia, Italy; Elvira Ventura spagnolo, MD, Messina University, Biomorf Department, Medico Legal Section, Messina, Sicilia, Italy; Domenico Abramo, MD*, Messina University, Messina, Sicilia, Italy; Gabriele Rotter, MSc, Messina University, Reggio Calabria, Calabria, Italy*

Learning Objectives: After attending this presentation, participants will gain a comprehensive understanding of the Integration of Forensic Epidemiology and the Rigorous Evaluation of Causation Elements (INFERENCE) model. They will also learn how the critical application of this method can support the implementation of a multidisciplinary approach and enhance the reproducibility and transparency of causal analyses. This, in turn, promotes evidence-based practice as a quality assurance measure, leading to the formulation of well-reasoned and objective expert opinions—particularly valuable in cases involving exceptional violence.

Impact Statement: This presentation will impact the forensic science community by emphasizing the necessity of multidisciplinary investigative strategies to understand and resolve such complex cases and adopting a systematic approach and a evidence-based framework. The aspects considered in the management of the case are discussed, along with a compared approach to the data provided by literature.

Abstract Text: Parricide remains among the rarest forms of homicide—more so when both parents are killed with extraordinary brutality. Such acts are frequently linked to diagnosed psychiatric conditions in the perpetrator. In this case, however, the son's schizophrenic disorder was previously unknown to relatives or authorities.[1] A literature review contextualizes the double homicide within broader forensic and psychiatric paradigms. Moreover, in light of recent efforts to raise standards in forensic practice, the INFERENCE model was applied, involving a multidisciplinary approach to determine whether the case in question was a murder-suicide, a single-perpetrator homicide, or a double homicide committed by multiple individuals.[2]

Case Report: The case involves the double homicide of a couple aged 66 and 62. Neighbors alerted police after hearing screams from the victims' residence. The crime occurred in the kitchen, where the couple was dining. Crimino-dynamic analysis conducted through police investigations, integrated with the forensic medical examination, Bloodstain Pattern Analysis (BPA), and DNA testing revealed that the homicide was carried out by a single perpetrator, later identified as the couple's son. The assailant abruptly entered the room and attacked both victims using a cleaver, which was later recovered at the scene. The attack unfolded around the dining table, after which the bodies were dragged and positioned together in a corner of the kitchen. Both victims exhibited similar trauma patterns: defensive wounds and deep penetrating injuries involving the skeletal system, particularly the skull. During autopsy, a striking finding in the female victim was the presence of her husband's hair embedded in the brain tissue. Histological examination revealed exogenous material within her cranial wounds, indicating that although testimonial evidence suggested she was the initial target, she was struck when the blade already carried external contaminants.

Conclusion: All case elements assessed allowed for the exclusion of the initial hypothesis of a murder-suicide—originally considered due to the husband's history of depression—and instead supported the classification of the event as a homicide. Genetic testing confirmed that all blood traces found at the crime scene were consistent with the biological profiles of the three family members. Further BPA indicated that the blood patterns were compatible with the presence of a single perpetrator at the scene. Finally, the multidisciplinary approach, which included witness statements and a psychological evaluation, suggested that the act was triggered by long-standing conflicts between the perpetrator and his mother, with the father likely targeted solely due to his presence. This evidence-based scientific process allowed the event to be classified beyond reasonable doubt as a double parricide marked by extreme overkilling.

B5 A Forensic Approach to Quantifying Environmental Tobacco Smoke Exposure in Hair: Method Development and Analysis of Cosmetic Treatment Effects

Tanique Z Jones, BSc, University of Texas at El Paso, El Paso, GA; Somayeh Mohammadi, PhD, University of Texas at El Paso, El Paso, GA; Hamidreza Sharifan, PhD, University of Texas at El Paso, El Paso, TX; Christopher J Trejo, BSc, University of Texas at El Paso, El Paso, TX*

Learning Objectives: This goals of this presentation are to: explain the scientific rationale for using human hair as a biological matrix for long-term exposure assessment to Environmental Tobacco Smoke (ETS) in forensic contexts; cover the application of Ultraviolet/Visible (UV/Vis) spectroscopy, Fourier Transform Infrared (FTIR) analysis, and zeta potential measurement techniques in detecting and quantifying ETS residues on chemically treated (dyed/bleached) and untreated hair; compare the adsorption capacity of dyed, bleached, and untreated hair exposed to ETS and interpret how chemical treatments alter hair's physicochemical properties and impact forensic analysis; and explore the forensic implications of differential smoke residue retention in hair samples, including their use in legal investigations, custody disputes, or environmental exposure cases Attendees can apply the presented lab method as a teaching tool or investigative approach in forensic science education and practice, particularly in toxicological or trace evidence analysis.

Impact Statement: This presentation introduces a novel, low-cost, and reproducible laboratory method for quantifying ETS exposure using human hair as a biological matrix, with direct applications in forensic science. By integrating UV/Vis spectroscopy, FTIR analysis, and zeta potential measurements, the study demonstrates how cosmetic hair treatments significantly affect the retention of smoke residues—an overlooked variable in exposure assessment. The method not only enhances the forensic toolkit for long-term toxicological analysis but also provides an accessible educational model for forensic chemistry instruction. This work empowers forensic professionals to more effectively interpret trace evidence related to environmental exposures, thereby strengthening the scientific basis for using hair analysis in legal and investigative contexts, including custody cases, workplace exposure disputes, and public health forensics.

Abstract Text: ETS poses well-documented health risks and remains a concern in both public health and forensic investigations. This study develops and demonstrates a reproducible laboratory method for quantifying ETS exposure through hair analysis, integrating UV-Vis spectroscopy, FTIR spectroscopy, and zeta potential measurements. Hair samples categorized as untreated, dyed, and bleached were exposed to cigarette smoke in a controled environment for intervals of 15, 30, 45, and 60 minutes. Quantitative analysis revealed that dyed hair exhibited the highest absorbance at 280 nm, measuring 3.2 times higher than bleached hair and 1.8 times higher than untreated hair after 60 minutes of exposure. FTIR spectra showed notable alterations in the amide I and II regions (1700–1500 cm^{-1}), particularly for dyed and bleached hair, confirming smoke-induced chemical modifications. Zeta potential measurements further supported these findings, with dyed hair shifting from +0.4 mV to +2.6 mV**,** untreated hair from +1.7 mV to −6.2 mV, and bleached hair from −20.6 mV to −22.3 mV after smoke exposure. These results indicate that chemical treatments alter hair's physicochemical properties, significantly enhancing its ability to adsorb smoke residues. The method offers a non-invasive, reliable means for long-term exposure assessment and serves as a valuable teaching and investigative tool in forensic chemistry. This approach enables detailed environmental exposure profiling and can be applied in legal cases where ETS exposure is contested or needs to be reconstructed.

B6 Close Non-Matches and Database Searches: Probability That a True Match Is Among the Top K Correlations After a Database Search

Blanca I. Parker, BA, Iowa State University, Schenectady, NY; Alicia L. Carriquiry, PhD, Iowa State University, Ames, IA;Heike Hofmann, PhD, University of Nebraska- Lincoln, Lincoln, NE*

Learning Objectives: Participants will learn about the prevalence of close non-matches and gain insight into the reliability of database searches for ballistic and fingerprint evidence. They will learn about a general trend across pattern evidence where, as databases grow, they become less reliable at finding true matches. The goal of this presentation is for participants to understand the impact of increasing database size on the accuracy of search results and learn at what times it is appropriate to take heightened caution to avoid close non-matches.

Impact Statement: This presentation will be impactful to the forensic science community by bringing awareness to the potential for contextual bias when conducting database searches. It will share insight about the increasing risk of close non-matches overshadowing a true match with increasing database size. Bringing awareness to the importance of database size in producing close non-matches could help to avoid situations where forensic examiners may be persuaded to find correlations that are not really there.

Abstract Text: Suppose a crime has been committed and examiners have recovered spent bullets, cartridge cases or fingerprints from the scene. To generate investigative leads, examiners often rely on proprietary systems such as the National Integrated Ballistics Information Network (NIBIN) and Automated Fingerprint Identification System (AFIS) to correlate a piece of evidence to potentially similar bullets or fingerprints recovered from other sources. Investigators upload images of the crime scene item(s) onto the system, request a list of the top k most similar items from the database, then decide whether any of the k candidates are similar enough to the questioned items to warrant a physical comparison.

But how reliable are database searches? Suppose that one or more true matches to a questioned piece of evidence are in the database. How likely are those true matches to be included in the list of the top k correlations identified by the system? To explore this question, we carried out a simulation where we varied the potential number of correlations (N), the size of the list of candidates (k) and the number of true matches in the database (t). Previously, we used beta probability models to represent the distribution of Same Source (SS) and Different Source (DS) similarity scores for bullets, with parameters fixed at values that would reproduce the scores calculated from data obtained by Fadul and Weller and presented in Song et al., after rescaling.[1] We have expanded our study to include other plausible models for the DS and SS distributions. We use a Beta-Binomial model to represent the distribution of similarity scores in known matches and a Binomial model to present the distribution of similarity scores in known non-matches also from Song et al.[1] To model SS and DS scores calculated from the Hamby-44-CSAFE dataset set, we fit beta probability models. [2] Finally, to simulate the search of a fingerprint database, we also fit beta probability models to DS and SS similarity scores calculated with FRStat.[3] Beta parameters are selected by rescaling distributions of distributions of Global Similarity Score Statistics in Swofford et al.[3]

We fixed databases sizes at N = 500, 5,000, 50,000 and 500,000, and for each, requested the top k = 10, 20, 50, 100 most similar items when N-t items were sampled from the DS distribution and t from the SS distribution. Our findings suggest that at least four factors, including the size of the search space N, the number of candidates k, the number of true matches in the database t and the degree of overlap between the DS and the SS distributions, have an effect on the probability that a true match appears in the candidate list. For different distributions and types of evidence, we see the same general trend where reliability decreases as database size increases.

B7 Toward a New Forensic Tool: Elemental Profiling of Tire Rubber in Traffic Homicide Cases

John G. Lucchi, PhD, National Center for Forensic Science, Orlando, FL; James McAleer, BS, National Center for Forensic Science, Orlando, FL; Matthieu Baudelet, PhD, University of Central Florida, Orlando, FL*

Learning Objectives: Attendees will learn how elemental profiling of tire rubber using Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) has the potential to be applied in forensic investigations to accurately classify tires, enhancing the ability to link tire residues from accident scenes to specific vehicles involved in hit-and-run incidents.

Impact Statement: This study demonstrates that tire rubber carries unique elemental signatures that remain consistent across the tire circumference, enabling reliable classification with over 90% accuracy. Incorporating this analytical approach into forensic workflows can provide investigators with a powerful supplementary tool for identifying vehicles in hit-and-run cases, ultimately improving case resolution and delivering justice for victims.

Abstract Text: Between 2004 and 2022, nearly 33,000 fatalities in the United States were linked to hit-and-run incidents, underscoring the urgent need for more precise and detailed analysis of road accident scenes. Determining fault is essential to securing justice for victims. While traditional tire mark analysis relies primarily on physical reconstruction of collisions, chemical analysis of rubber residues offers a powerful complementary line of evidence. By examining tire particles and linking them to their original sources, investigators may be able to identify vehicles involved in hit-and-run cases.

Tires vary in composition depending on their brand and model, with each formulation designed for specific performance needs. Moreover, trace elemental contaminants introduced during manufacturing can serve as unique chemical fingerprints, enabling association of tire fragments with their sources. While molecular analysis of rubber has been used for tire classification, elemental profiling offers a highly sensitive method for distinguishing between manufacturers and models. In this study, ICP/MS was applied to analyze these elemental signatures, achieving over 90% classification accuracy across 36 tire models.

A key question in this work was whether trace elements within tires are evenly distributed along the circumference, as tire marks at crash scenes can originate from any section of the tread. To address this, 15 tires were sampled at eight locations along their circumference, and their elemental profiles were analyzed. While some elemental inhomogeneity was observed, it did not significantly impact classification accuracy.

These findings demonstrate that tire rubber can be quantitatively analyzed for forensic purposes. This novel approach has the potential to enhance forensic investigations, providing practitioners with a reliable method to aid in resolving hit-and-run cases with greater accuracy and confidence.

B8 Washington DC Department of Forensic Sciences: A Strategic Approach to Optimizing Laboratory Operational Efficiency—DC DFS's Implementation of the Casework Administration Group

Krystyna Hopkinson, MSFS, DC Department of Forensic Science, Washington, DC*

Learning Objectives: After attending this presentation, the audience will understand how a crime laboratory can optimize operations to maximize casework output through the implementation of a team of technicians that float between the technical units of the forensic laboratory.

Impact Statement: This presentation presents a laboratory model that, when implemented, creates positive impacts, including successfully maximizing casework output and reducing the backlog without sacrificing high-quality forensic testing services.

Abstract Text: The Washington, DC, Department of Forensic Science's (DFS), Forensic Science Laboratory (FSL) is made up of five technical and non-technical units: Forensic Biology Unit, Forensic Chemistry Unit, Latent Fingerprint Unit, Forensic Intelligence Unit, and the Casework Administration Group. Like many forensic crime laboratories across the country, the DFS FSL is faced with a large volume of casework with finite resources. To understand the use of resources, DFS FSL examined the daily routine of caseworking analysts across all DFS FSL technical disciplines to identify technical and non-technical assignments and bottleneck points. The analysis showed that in addition to traditional laboratory benchwork, casework analysts across all disciplines perform non-technical assignments each day ranging from evidence transfer coordination (both within the agency as well as with external submitting agencies), receiving deliveries, restocking the laboratory with reagents and consumables, washing laboratory glassware, and addressing biohazard and chemical waste disposals as well as assisting with complex, comprehensive discovery requests. Performing these non-technical laboratory functions takes time away that could be dedicated to casework assignments.

To provide analysts with more dedicated time to focus on casework assignments and maximize output, the DFS FSL established the Casework Administration Group (CAG), a team of technicians that float between the technical units performing many of the non-technical tasks. CAG technicians are entry-level scientists that receive cross-training in each of the technical disciplines as well as front-end operations such as testing requests. The CAG technicians follow components of each unit's training program and work closely with the discipline-specific Technical Leader in the development of customized Individual Training Plans (ITPs) based on their education and specific role within the unit. The unit-specific training allowed CAG to assist with tasks such as evidence handling and inventory, report dissemination, and biohazard and chemical waste removal. The implementation of CAG has been beneficial to the technical units who now have more time committed to address casework as well as the CAG technicians who gain experience and exposure to multiple forensic disciplines as part of their career development.

B9 Prints That Matter: Identifying the Most Productive Evidence Through Analytical Reporting

Angelic M. Rountree, BS, DC Department of Forensic Science, Washington, DC*

Learning Objectives: Attendees will learn how to utilize latent print recovery data to identify which types of physical yield the highest success rates for comparison, enabling more strategic and efficient forensic testing. They will gain practical knowledge on leveraging Laboratory Information Management System (LIMS) -based reporting tools to inform evidence prioritization and improve communication with stakeholders.

Impact Statement: This poster presentation will enhance the forensic science community's ability to make data-driven decisions when selecting evidence for latent print analysis, increasing both efficiency and effectiveness. By applying LIMS-based reporting to identify high-yield evidence types, practitioners can optimize resource allocation, reduce turnaround times, and provide more impactful results to investigators and stakeholders.

Abstract Text: In forensic science, maximizing efficiency and impact is essential, especially in latent print units, where time, staffing, and resources are often constrained. Over the past two years, the Latent Fingerprint Unit (LFU) of the DC Department of Forensic Sciences has undertaken a strategic effort to measure the success rate of latent print recovery from different types of evidence. This includes comparing results from items such as firearms versus magazines and porous surfaces like paper versus non-porous items like currency. The primary goal was to inform more targeted forensic testing decisions and optimize case outcomes by identifying which categories of evidence most consistently yield suitable latent prints for comparison.

Traditionally, forensic requests often include a wide range of items, sometimes referred to as including "everything but the kitchen sink " which can overwhelm resources and dilute efficiency. To address this, the LFU sought to leverage data already captured in its JusticeTrax LIMS to produce crystal reports that evaluate latent print recovery success over designated timeframes. By aligning processing outcomes with predefined evidence categories, the team aimed to assess trends in print suitability across different object types and substrates.

Working in partnership with the DFS Office of the Chief Information Officer (OCIO), the LFU developed a system to subcategorize evidence types based on porosity—an essential factor in determining appropriate latent print processing techniques. This modification allowed the LIMS to correlate evidence characteristics with latent print findings entered into final reports. The result is a data-driven reporting system that offers real-time insights into which types of evidence are most likely to yield viable latent print results.

This tool will significantly enhance communication between forensic analysts, crime scene units, and external stakeholders. Scene technicians can prioritize evidence most likely to be fruitful, while stakeholders such as investigators and prosecutors can tailor their evidence requests based on empirical success rates rather than assumptions. Ultimately, this initiative promotes smarter forensic triaging, reduces unnecessary testing, and enhances the overall impact of latent print analysis in criminal investigations.

Latent Print Recovery; Evidence Prioritization; Forensic Data Analysis

B10 The Relationship Between the Ridge Patterning and the Frequency of Minutiae on the Interdigital Area of Palmprints

Angela Tonietto, MSc, Sam Houston State University, Huntsville, TX; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: Attendees will learn about the importance of considering the frequency of occurrence of the most relevant characteristics in different human populations, especially the characteristics related to minutiae (Level 2 detail), for addressing source-level questions between palm marks recovered at crime scenes and reference palmprints.

Impact Statement: Beyond relying on an examiner's personal understanding of the rarity of friction ridge features in palms, practitioners can also use objective metrics about their respective frequencies in a specific population, especially considering the variety of minutia types observed in palm marks recovered from crime scenes.

Abstract Text: Minutiae are highly variable features in friction ridge skin. Minutia types vary qualitatively, quantitatively, and topologically, and they are influenced by level 1 detail, sex, and ancestry. The present research investigated the relationship between the ridge patterning (Level 1 detail) and the frequency of minutiae (Level 2 detail) on the volar pad IV of the interdigital area of palmprints in order to further develop the knowledge about the frequency of the most relevant characteristics for the process of identification by palmprints, particularly, the characteristics related to minutiae.

A total of 80 high-quality palmprint images, collected from 40 individuals (20 men and 20 women, aged 18 to 35), were analyzed. Frequencies of the general patterns—loop, composite, whorl, columns, no pattern—and 21 minutia types were calculated per hand and sex. Chi-square and Fisher's exact tests were applied to assess associations between minutia type and sex as well as between minutia type and the general pattern. The results revealed that loops and no pattern were present in 90% of the volar pad IV analyzed. Left-hand palmprints contained about 18% more minutiae than right-hand ones, and female palmprints had about 2% more minutiae than male counterparts in the volar pad IV. As expected, ridge ending was identified as the most frequent minutia type overall, followed by bifurcation. Convergence, crossbar, dock, and fragment small were the minutia types significantly associated with sex, and the rank order of minutiae frequencies differed between male and female palmprints. Fragment big, fragment small, and point in between showed a statistically significant association with the general ridge patterning.

These findings suggest that both sex and general pattern play a role in influencing minutiae distribution in the volar pad IV of the interdigital area of the hand. Also, less frequent minutia types held higher selectivity, particularly when combined with factors such as general pattern, sex, and hand (left/right). Finally, a standard approach for the classification of minutia types is deemed urgent to enhance comparisons between different human populations. Thus, future research should aim to bridge this gap by expanding sample sizes and improving classification methodologies.

B11 Cracking the Fingerprint Clock: Age-Dating Latent Fingerprints Using Multivariate Chemical Degradation Models

James Nketsiah, MPhil, Kwame Nkrumah University of Science and Technology, Kumasi, Ashanti, Ghana*

Learning Objectives: By the end of this presentation, attendees will be able to: identify key chemical constituents in latent fingerprint residue that are relevant for age estimation under uncontrolled environmental conditions; explain how multivariate modeling techniques, specifically Principal Component Analysis (PCA) and exponential regression, were applied to Gas Chromatography/Mass Spectrometry (GC/MS) data to estimate the age of latent fingerprints; compare the accuracy and forensic applicability of the presented fingerprint age-dating model with previously published chemical degradation models; and assess the practical value, limitations, and potential challenges of using chemical degradation data to estimate time since fingerprint deposition in forensic casework.

Impact Statement: This presentation explores an emerging approach for estimating the age of latent fingerprints using multivariate chemical degradation models. By applying GC/MS analysis alongside PCA and exponential regression, the study demonstrates a promising framework for modeling time-dependent changes in fingerprint composition. Although the models are still undergoing validation, the findings contribute critical insight into the chemical aging process of latent prints and lay the groundwork for future development of forensic age-dating tools. This research may ultimately support more accurate timeline reconstruction in forensic casework

Abstract Text: Latent fingermarks have long been central to forensic identification, yet their inability to indicate the time of deposition remains a significant limitation.[1] While fingermark identification is generally reliable, no scientifically validated method currently exists for estimating when a fingermark was left.[2] This issue is critical for assessing evidentiary relevance.[3] In the absence of empirical aging methods, forensic testimony often relies on subjective interpretation rather than objective data, which leads to inconsistent conclusions in courts across jurisdictions such as the United States and Ghana.[4,5]

This study addresses this gap by investigating whether the chemical degradation of specific fatty acids can be used to estimate fingermark age under tropical environmental conditions. Sebaceous fingermarks from male and female volunteers were deposited on non-porous microscopic slides and analyzed over 144 hours using GC/MS. Degradation patterns of hexadecanoic, oleic, and stearic acids were modeled using a four-tiered approach: multiple linear regression to assess the influence of individual compounds; curve estimation to evaluate temporal trends; PCA to extract a latent degradation factor; and multivariate non-linear regression to estimate fingermark age using sex-specific models. All three fatty acids showed measurable degradation over time with distinct patterns observed between sexes. The integrated PCA and exponential regression model explained 87%t of the variance in age prediction overall ($R^2 = 0.87$), with higher accuracy for males ($R^2 = 0.936$) than for females ($R^2 = 0.83$). Sex-stratified models improved predictive performance, reflecting underlying biological differences and outperformed existing univariate models. These preliminary multivariate models offer strong potential for objective fingermark age estimation and may support future forensic and legal applications, pending further validation.

B13 Gender Classification From Fingerprints In the East Indian Population

Roshni Butt, PhD, Adams University, Sagar, Madhya Pradesh, India*

Learning Objectives: Attendees will learn how Fingerprint Ridge Density (FPRD) can be used to classify gender. The presentation will cover methods of data collection and analysis and highlight key findings on sexual dimorphism in fingerprint patterns. Practical application in forensic identification and the reliability of fingerprint-based gender prediction will also be discussed.

Impact Statement: This study enhances forensic identification by demonstrating the reliability of FRPD for gender classification in the East Indian population, supporting the development of population-specific biometric tools in forensic science.

Abstract Text: In recent years, many studies have helped identify individuals through fingerprint features. The goal of this study is to determine gender based on ridge count in the East Indian population. The study highlights the significance of fingerprint patterns, which are unique to every individual, making them a vital biological characteristic in forensic science. This study investigates the presence of sexual dimorphism (differences between males and females) based on FPRD and evaluates its potential application in forensic investigations. This research was conducted on 100 participants (50 males and 50 females) from the East Indian population. Rolled fingerprints were collected from individuals aged 18 to 25 years from West Bengal and neighboring states. Using Bayes' Theorem, this study suggested that fingerprints having ridge density < 13 ridges/ 25 mm^2 are more likely of male origin, and > 14 ridges/25 mm^2 are more likely of female origin.[1] This study primarily aimed to determine the reliability of FPRD in identifying an individual's gender.

B14 Hand Detail Image Comparisons: The State of the Discipline for an Emerging Forensic Methodology

Nicole M. Richetelli, PhD, Noblis, Reston, VA; William Chapman, APM, Noblis, Reston, VA; Richard W. Vorder Bruegge, PhD, ForensicVB LLC, Fredericksburg, VA; Jim Cole, Onemi-Global Solutions, Mt Juliet, TN*

Learning Objectives: After attending this presentation, attendees will understand the current state of the discipline for hand detail image comparisons, including details regarding image comparison training, practice, utility, policies and procedures, standardization, and the prevalence of different types of casework. Attendees will also gain information about how they can contribute to the study.

Impact Statement: This presentation will impact the forensic science community by describing the current state of the discipline for image comparison casework, with a specific focus on hand detail image comparisons. These results will provide essential baselining information to laboratory managers, practitioners, standards organizations, and the legal system regarding the utility and practice of hand detail image comparison, an emerging discipline of forensic science that is seeing increased use in the United States and abroad.

Abstract Text: Can photographs of hands be used by forensic analysts to accurately and reliably identify or eliminate individuals? Hand detail image comparisons are seeing increased use in forensic science, both in the United States and abroad, specifically in cases involving child exploitation, sexual assault, kidnapping, and terrorism. In these cases, forensic examiners are asked to determine whether they can identify or eliminate a specific person using only images of their hands. This type of comparative analysis could be critical for solving these types of cases, but we need a better understanding of how this is being done in practice.

To this end, Noblis is currently conducting the *Forensic Hand Detail Image Comparison Study*, under a grant from the National Institute of Justice (NIJ Grant #15PNIJ-24-GG-03846-NIJB); this study is a rigorous, comprehensive evaluation of the emerging discipline of hand image comparisons. The goals of this study will be achieved in multiple phases, specifically designed to characterize the current state of the field, assess the decision space and reliability of analyst opinions, evaluate the requisite experience for conducting these comparisons, and understand the current limitations.

This presentation will specifically focus on the first research phase of the ongoing study: the Hand Image Comparison State of the Discipline Questionnaire (SDQ). The SDQ is being disseminated to United States and Canadian forensic laboratories, intelligence/law enforcement agencies, and independent practitioners in order to collect information about how many agencies are conducting these types of comparisons and how they are being done in practice. This presentation will detail the SDQ results, specifically providing empirical data regarding image comparison training, practice, utility, policies and procedures, and the prevalence of different types of operational casework.

These results are expected to provide essential baselining information to laboratory managers, practitioners, researchers, standards organizations, and the legal system regarding the utility and practice of hand detail image comparison, a relatively new and emerging discipline of forensic science.

B15 Reaping the Research: Patent Landscape Analysis of Latent Fingerprint Processing Techniques (1900–2024)

Jatin Kumar Sharma, MSFS, Central Finger Print Bureau, National Crime Records Bureau, Gurugram, Haryana, India; Abhilasha ., MS, Central Finger Print Bureau, National Crime Records Bureau, Gurugram, Haryana, India*

Learning Objectives: Attendees will gain a comprehensive understanding of the evolution of patented technologies for latent fingerprint processing over the past century. Our attempt will be to interpret research-to-product trends, identify innovation gaps, and assess the global and regional trajectories in fingerprint science using patent data.

Impact Statement: This presentation will assist fingerprint researchers in identifying potential funding channels and translational pathways to convert their laboratory research into patentable and commercially viable products. By mapping historical and current patent trends, the session will highlight mechanisms through which academic innovation has been successfully protected and funded, including governmental innovation grants, public–private partnerships, and industry-led incubation programs. Simultaneously, the analysis will benefit industry partners by showcasing pathways to collaborate with academic institutions, support promising technologies, and develop shared platforms for screening and investing in high-impact patents. This dual approach ensures that high-quality research published in peer-reviewed journals does not remain confined to academic circles but is actively translated into deployable solutions for law enforcement and forensic institutions. Select case studies—such as how a laboratory concept evolved into one of Sirchie's most widely adopted fingerprint visualization kits—will be used to illustrate successful research-to-product pipelines.

Abstract Text: Latent fingerprint visualization is a foundational practice in forensic science, widely utilized in criminal and civil investigations. While scientific literature has long documented the evolution of visualization methods from powder dusting to chemical reagents and instrumental analyses, there has been comparatively less focus on the patent landscape, which serves as a real-world indicator of technological advancement and commercial translation.[1-4] This study seeks to bridge that gap by conducting a global patent landscape analysis of latent fingerprint visualization technologies spanning from 1900 to 2024.

Drawing from Google Patents, Espacenet, and India's InPASS database, we analyzed over 400 patents using both quantitative and qualitative methods.[3-5] The research proposition was that patent data can reveal overlooked innovation trends, region-specific research priorities, and the progression of forensic fingerprint technology over time.[6] The analysis focused on four primary domains: (1) types of technologies patented, (2) filing and grant trends over time, (3) geographical distributions, and (4) key innovations in materials and methods.

Our findings highlight a shift from classical powder- and cyanoacrylate-based techniques in the early and mid-20th century toward more recent innovations involving nanomaterials, luminescent tagging agents(and AI-powered image enhancement tools.[7-9,12] Notably, the 2000s witnessed a sharp increase in patents related to eco-friendly and portable visualization kits, particularly from India and Southeast Asia, reflecting both regional forensic needs and growing environmental consciousness.[10,11] Meanwhile, the United States and select European nations showed significant patent activity around quantum dot formulations and multifunctional substrates aimed at improving contrast, adhesion, and specificity.[7,8]

Furthermore, the study identifies periods of innovation stagnation and surges, often correlating with major international forensic advancements or regulatory shifts.[12] For example, spikes in patent filings were noted around the time of standardization movements and global forensic quality assurance initiatives.[13] Our analysis also uncovered several patents that, while granted, have not translated into commercial or operational use, signaling potential gaps between invention and implementation.

In conclusion, patent landscape analysis emerges as a powerful yet underutilized tool in forensic science.[4,6] It complements academic literature by offering insight into what technologies are being protected, where investment is flowing, and which forensic challenges innovators are prioritizing. By understanding this broader innovation ecosystem, forensic professionals, researchers, and policymakers can better allocate resources, encourage targeted research, and adapt practices to incorporate novel technologies.

B16 The Washing Away of Evidence: The Effect of Different Washing Treatments on Body Fluid Identification and DNA Profiling From Stained Clothing Fabrics

Sara C. Zapico, PhD, New Jersey Institute of Technology, Newark, NJ; Francisco Medina-Paz, PhD, New Jersey Institute of Technology, Newark, NJ; Maria Josefina J. Castagnola, MSc, New Jersey Institute of Technology Harrison, NJ; Gabriela Roca, MD, PhD, SERATEC, Göttingen, Niedersachsen, Germany; Vasilisa Yukhno, New Jersey Institute of Technology, Newark, NJ*

Learning Objectives: After attending this presentation, attendees will be informed about how different types of washing treatments could affect the detection of body fluids on fabrics and how this impacts DNA profiling.

Impact Statement: This presentation will impact the forensic science community by presenting for the first time a complete study evaluating the effect of washing treatments on body fluids encountered at crime scenes, on different types of fabrics, also demonstrating the possibility of DNA profiling, independently of body fluid detection.

Abstract Text: Body fluid detection, like blood, semen, and saliva, is valuable for the investigation of criminal cases to identify the perpetrator, and in certain cases, the victim. Aware of the latter, suspects could clean their bodies and clothes after committing a crime to alter the evidence or avoid its detection. This action could hamper the detection of these fluids by different methods. In fact, little is known about the extent of serological testing of clothing fabric samples stained with body fluids after they have been washed. Many of the studies in this area were focused on the use of alternative light sources and/or chemical assays on the assumption that washing destroys or reduces the concentration of the components. From another part, even though it has been demonstrated previously that DNA can be recovered from clothing laundered after the deposition of some body fluids, cleaned items are not routinely analyzed for DNA profiling.

The aim of this study was to evaluate the effect of four different washing treatments on: (1) body fluid identification using lateral Flow Immunochromatographic (LFI) tests; (2) human DNA extraction yield; and (3) the integrity of the generated genetic profiles on three types of body fluids (blood, semen, and saliva), four volumes (20 ul, 50 ul, 5 ml, and 10 ml), and three common types of fabric (cotton, denim, and polyester). Our results indicated that the two smallest volumes subjected to machine–laundering in cotton, denim, and polyester, even if no detergent is used, reduces the concentration of the major components from blood, saliva, and semen, making difficult the identification of the protein related to the body fluids identification by LFI. In contrast, when large volumes were tested, identification was possible. Importantly, for small volumes of body fluid used in this evaluation, it was possible to isolate human DNA from blood-, saliva-, and semen–stained cotton and denim fabric with quality and quantity good enough to obtain partial and even full Short Tandem Repeat (STR) profiles. Both washed and unwashed samples showed no correlation between LFI band intensity results and human DNA concentration.

Our findings suggest that body fluid identification and genetic profiling can still be performed after clothes with small stains are washed. This protocol could be applicable to real-case scenarios by considering body fluid volumes and washing treatments that simulate what would be found in common crime cases.

B17 The Differentiation of Cell Populations in Saliva-Skin Mixture Samples Using Cellular Autofluorescence Profiling

Kara Fairfax, BS, Virginia Commonwealth University, Richmond, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA; Arianna DeCorte, MS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: After this presentation, attendees will understand how techniques such as autofluorescence profiling can be utilized to identify contributor cell populations originating from different tissue sources. Attendees will also learn how these signatures can be used to physically isolate contributor cell populations from samples obtained in certain types of sexual assault casework involving mixtures of saliva and skin cells.

Impact Statement: This presentation will impact the forensic science community by describing a new strategy for improving analysis of complex biological mixtures, particularly those that result from deposition of saliva onto the skin surfaces. This technique could allow forensic laboratories to quickly screen samples for the presence of saliva and/or associate a DNA profile with a specific type of source tissue. This can increase the efficacy of DNA profiling and potentially reduce the need for mixture interpretation protocols for many types of sexual assault samples.

Abstract Text: Analysis of evidentiary sexual assault samples that result from oral contact can pose a significant issue in forensic casework when the resulting DNA profiles represent multiple contributors that are difficult to interpret. A new method is needed that can detect the presence of saliva deposits in a skin swab and physically isolate these cell populations on the front end of a DNA workflow. One promising strategy for this is morphological and/or autofluorescent signatures that differentiate cells associated with the oral cavity (e.g., epithelial cells sloughed from the tongue) from skin epidermal cells. Although skin, saliva, and tongue cells are all epithelial cells, each of these tissue sources is associated with unique structural and/or biochemical properties that can be detected using the autofluorescence profiles of individual cells. The goal of this study was to build autofluorescent signatures for these epithelial cell types that are specific to the oral cavity and test whether they can be used to: (1) detect saliva when it is deposited on skin and, therefore mixed, with epidermal cells; and (2) physically isolate contributor cell populations from two-person mixtures.

To accomplish this, saliva, tongue, and epidermal cells were collected from 30 individuals and allowed to age for between two days and one month. Skin samples were collected by swabbing the underside of the arm. Tongue epithelial cells were deposited by having the donors lick the convex side of a spoon and saliva samples were collected by pipetting 200 µL of saliva onto a clean glass slide. Each cell population was then eluted from the swab by vortexing in 1X PBS and analyzed immediately using flow cytometry. Autofluorescence profiles were characterized using five excitation lasers (Ultraviolet [UV]- 355 nm, Violet- 405 nm, Blue- 488 nm, Yellow-Green- 561 nm, and Red- 640 nm) and emission wavelengths between 365 nm and 829 nm.

Single-source samples were first compared to develop tissue-specific signatures. Results showed that cell populations derived from saliva had a greater proportion of cells with larger areas (>100um) compared to cell populations from both skin and tongue surfaces. The saliva cell populations also exhibited a higher intensity of autofluorescence within the UV and Violet emission channels, and a greater proportion of cells with a high side scatter and a high intensity of autofluorescence, above 105 Relative Fluorescence Units (RFU), in the fourth violet excitation channel (466-481 nm). Results also showed that cell populations from tongue deposits had lower intensity autofluorescence within the UV and Violet emission channels when compared to skin deposits (10 RFU compared to 100 RFU) as well as a higher proportion of cells with larger areas (>100um) observed as a result of forward scatter and a lower proportion of cells with larger areas (>100um) observed as a result of side scatter. Lastly, results from analysis of ten different saliva-skin mixtures indicated that saliva epithelial cells could be detected in skin swab samples in each contributor combination tested and when saliva was diluted prior to deposition (e.g., 1:10, 1:100).

B19 A New Spin on DNA Extraction: Validating SpermX GenSpin Differential Extraction for Sexual Assault Evidence Processing

Tori E. Tyree, BS, Marshall University, Ona, WV; Amy McGuckian, MFS, Palm Beach County Sheriff's Office, West Palm Beach, FL; Julie Sikorsky, MSc, Palm Beach County Sheriff's Office, West Palm Beach, FL; Kelly J. Beatty, MSFS, Marshall University, Huntington, WV*

Learning Objectives: Attendees will learn how the SpermX GenSpin Differential Extraction protocol utilizes nanofiber membrane technology to enhance sperm cell isolation and improve male DNA recovery from mixed biological samples. This presentation will explain how the GenSpin method differs from traditional differential extraction techniques and highlight its performance across validation studies, including sensitivity, precision and accuracy, mixture analysis, and mock casework. Attendees will also gain insight into how this streamlined, high-yield protocol reduces epithelial DNA carry-over and increases Short Tandem Repeat (STR) profile completeness, offering a more efficient and consistent approach for processing sexual assault evidence in forensic laboratories.

Impact Statement: This poster will provide forensic practitioners with evidence-based insight into an innovative manual differential extraction method that enhances male DNA recovery and profile completeness from sexual assault evidence. By presenting the effectiveness and operational advantages of the SpermX GenSpin protocol, this work supports laboratories in adopting more efficient and reproducible workflows. The findings have the potential to improve the quality, consistency, and reliability of DNA results, contributing to advancements in sexual assault kit processing and forensic laboratory practices.

Abstract Text: The purpose of this study was to evaluate male DNA recovery from sexual assault evidence samples utilizing the SpermX GenSpin Differential Extraction protocol in comparison to traditional manual differential extraction methods. This study presents an internal validation of the SpermX GenSpin protocol, which uses a nanofiber membrane to selectively capture sperm cells while allowing epithelial cell DNA to pass through. This selective trapping mechanism enhances sperm cell isolation, improves male DNA recovery, and results in cleaner separation of male and female DNA fractions.

Sexual assault evidence frequently contains mixed biological material, requiring differential extraction to separate sperm cells from epithelial cells.[1] Traditional differential extraction methods are often labor-intensive, time-consuming, and susceptible to variability in male DNA yield.[1] The SpermX GenSpin Differential Extraction protocol offers a novel, manual differential extraction method that streamlines processing while enhancing sperm cell isolation and male DNA recovery.

This validation study assessed the protocol's performance across a range of studies, including sensitivity, precision and accuracy, mixtures, and mock casework. The SpermX GenSpin Differential Extraction method consistently produced higher male DNA yields and more complete Short Tandem Repeat (STR) profiles, with reduced carry-over from epithelial DNA. Its simplified workflow offers a high-yield alternative to traditional labor-intensive differential extraction methods.

These findings support the SpermX GenSpin protocol as an effective and high-performing manual differential extraction method for processing mixed biological evidence containing seminal fluid. Its robust performance and operational efficiency make it a potential tool for improving the quality and consistency of forensic DNA results in sexual assault cases.

B20 Cell-Free DNA From Clinical Sperm Samples

Xuxiang W. LI, MS, Boston University, Kent, WA; Robin W. Cotton, PhD, Boston University, Boston, MA*

Learning Objectives: The attendees will learn that seminal fluid contains cell-free DNA (cfDNA). The cellular sources and amounts of the cfDNA are variable. Awareness of seminal fluid cfDNA may assist in explaining unusual results in differential extractions.

Impact Statement: cfDNA is likely to be present in sexual assault evidence samples. Some of this non-cellular DNA will be detected by quantitative Polymerase Chain Reaction (qPCR) but may not be differentiated from other male DNA in the sample.

Abstract Text: cfDNA was first identified in human blood by Mandel and Metais in 1948, and its presence has subsequently been documented across various human bodily fluids. Despite extensive application in oncology and non-invasive prenatal diagnostics, the forensic application of cfDNA remains comparatively limited. Currently, the forensic use of cfDNA primarily targets evidence recovered from surfaces that individuals have contacted. In contrast, cfDNA from bodily fluids—particularly semen—has not been fully integrated into forensic DNA analysis practices.[1,2]

This presentation examines the forensic potential of cfDNA in semen. cfDNA in semen is hypothesized to originate from either epithelial cells within the seminiferous tubules and reproductive tract or from ruptured sperm cells resulting from stress conditions before or after sample collection.[3]

To evaluate this hypothesis, 28 clinical samples from the Department of Urology at Boston University School of Medicine were analyzed. DNA quantities from 5 ul of a 1:5 dilution of each sample were examined using two methods. For each sample, DNA in ng was calculated from sperm counts done using Metafer Software microscopy and was compared to quantitative PCR (qPCR) results after cell lysis of a second 5 ul sample utilizing the AcroSolv sperm lysis kit. (This is a direct cell lysis method that does not incorporate DNA purification). The difference in DNA mass using these two measurements was calculated. An additional comparison was made with DNA extracted using a common differential extraction method.

Results demonstrate that there are significant discrepancies between the microscopic sperm quantification values and total DNA quantities measured by qPCR, highlighting that the amount of DNA from sperm cells and the total DNA quantity in these clinical samples varies significantly. We note that these are preliminary results; however, the results indicate that there are significant amounts of cfDNA present in some of these clinical semen samples. More definitive characterization of these results is ongoing.

B21 Differential Extraction: A Comparison of SpermX and I-Sep DL-MB to Determine Cell Separation Efficiency and Kit Sensitivity

Evan M. Wheeler, MS, Edmond, OK; Rhonda Williams, PhD, University of Central Oklahoma, Edmond, OK*

Learning Objectives: After attending this presentation, attendees will understand the challenges that come with differential extraction and how recent advancements in DNA analysis kits have advanced the differential extraction process.

Impact Statement: This presentation will impact the forensic science community by serving as an example of how recent advancements in differential extraction kits can aid in cell separation efficiency and sensitivity to obtain DNA.

Abstract Text: Differential extraction is a modified organic extraction that was developed in 1985 to separate male DNA (sperm cells) from female DNA (epithelial cells) in mixed samples. This process presents challenges such as the loss of male spermatozoa cells, which are essential in sexual assault investigations, as well as the potential for epithelial cell carryover.[1,2] Recent advancements in DNA analysis kits have advanced the differential extraction process.

In this project, Biotype's Sampletype i-sep DL-MB and InnoGenomic's SpermX kits were compared to a traditional in-house differential extraction to determine cell separation efficiency and sensitivity.[3,4] The kits were also evaluated for ease of use and processing time. The protocol for each kit involved processing mixed samples with semen concentrations as follows: neat, 1/10, and 1/100 dilutions. Samples were extracted according to the kit protocols and quantified with Quantifiler Trio. The samples were then amplified utilizing PowerPlex Fusion 5C with subsequent genetic analysis.

Results obtained from triplicate testing show that SpermX is highly effective at isolating the sperm fraction from neat sperm samples, yielding an average of 1.07 ng/µl compared to 0.41 ng/µl with other methods. Conversely, the i-sep method outperforms SpermX in extracting DNA from the epithelial fraction. Notably, the DNA quantities from SpermX at 1/10 and 1/100 dilutions (0.12 ng/µl and 0.03 ng/µl, respectively) were similar to those from i-sep at the same dilutions
(0.09 ng/µl and 0.02 ng/µl), and both methods surpassed the traditional in-house approach.

Biotype's Sampletype i-sep DL-MB was the most user-friendly, easiest to incorporate into existing laboratory workflows, and had the shortest processing time. However, the i-sep method had some unconventional requirements, such as the inability to incubate tubes in a heat block and the necessity of heating the buffer to 56°C prior to use.[5] InnoGenomic's SpermX required a specialized centrifuge insert, supplied with the kit due to the custom tube size, and took approximately six hours to process—the longest among the three methods.[6]

In summary, although InnoGenomic's SpermX kit takes twice as long as Biotype's Sampletype i-sep DL-MB, it appears to be the most effective option for obtaining sperm profiles from sexual assault samples.

B22 From Swabs to Sequencing: Integrating Y-Screening and NGS Into Sexual Assault Evidence Processing

Lyndsy Stacy, MS, Sam Houston State University, Huntsville, TX; Joshua D. Boster, MS, Sam Houston State University, Kansas City, MO; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Jennifer L. Snedeker, PhD, Onalaska, TX*

Learning Objectives: After attending this presentation, attendees will understand how Y-chromosome-specific quantitative Polymerase Chain Reaction (qPCR) (Y-Screening) can be used to triage sexual assault evidence and guide downstream testing decisions. They will also learn how autosomal Short Tandem Repeat (STR) profiles were generated from a range of mock and post-coital samples using both capillary electrophoresis and Next Generation Sequencing (NGS) platforms.

Impact Statement: This presentation will impact the forensic science community by demonstrating an integrated workflow that combines Y-Screening, traditional STR typing, and NGS for the evaluation of sexual assault evidence. The study includes likelihood ratio calculations using STRmix and STRmix NGS to assess the probative value of STR profiles across platforms. This approach enhances the objectivity, scalability, and interpretive consistency of forensic DNA analysis, particularly in complex or mixture-heavy casework.

Abstract Text: Sexual assault kits (SAKs) are among the most frequently submitted forms of forensic evidence. However, traditional serological screening methods such as presumptive tests and microscopic sperm identification are time-consuming and subjective, with limited ability to predict downstream STR success. Y-chromosome-specific qPCR (Y-Screening) offers an alternative approach that enables quantitative detection of male DNA and supports more informed decisions about which samples to prioritize for DNA typing.

This study evaluated Y-Screening using the Investigator Casework GO! and Quantiplex Pro kits across a wide array of mock and authentic sexual assault sample types. These included vaginal, buccal, and hand swabs spiked with semen, male–female and male–male mixtures, and post-coital samples collected at multiple time intervals. Two screening strategies were compared: direct swab lysis and pellet-based sperm enrichment. Downstream STR typing was performed using the Investigator 24plex QS kit. Random match probabilities were calculated using ArmedXpert™ to evaluate the probative strength of the resulting autosomal profiles.

A subset of 80 samples was also processed using the ForenSeq MainstAY NGS workflow to assess compatibility with sequencing-based analysis. Initial results showed high concordance with CE-based profiles. Random match probabilities were calculated using MixtureACE™ to evaluate the probative strength of the resulting autosomal profiles and compare to those from CE.

While both Y-Screening approaches showed strong alignment with downstream STR success in most sample types, male–male mixtures presented unique challenges, as quantitation values alone were not always reliable predictors of sperm donor DNA presence. Nevertheless, the combination of Y-Screening and differential extraction provided consistent and scalable triage for complex evidence.

These findings demonstrate the value of integrating front-end screening with multi-platform STR typing in the evaluation of sexual assault evidence. The incorporation of CE and NGS-based typing platforms, supported by probabilistic interpretation, offers a roadmap for more efficient and objective forensic workflows. Ongoing work will focus on refining quantitative thresholds and validating NGS-based interpretation in complex mixtures, particularly in cases involving multiple male contributors.

B23 DNA Sample Success Rates and Selecting the Most Impactful Evidence for DNA Testing

Julie Ferragut, BS, DC Department of Forensic Science, Washington, DC*

Learning Objectives: The District of Columbia Department of Forensic Sciences (DFS) analyzed sample success rates for evidentiary types typically encountered at crime scenes. After attending this presentation, the participants will understand the value of communicating data trends to submitting customer agencies and how these data trends can assist their customers with evidence selection to provide the most impactful and meaningful results.

Impact Statement: The impact of the presentation on the field of forensic sciences is an explanation of how analyzing success rates for different evidentiary types can help inform customers of how to best select forensic samples for DNA testing.

Abstract Text: With the number of requests for DNA testing steadily increasing each year and the challenge of limited resources, the DFS analyzed the results from the most common evidentiary types submitted by its customers to evaluate success rates. For each sample that is tested, a metric is generated in the Laboratory Information Management System (LIMS) system from which data was able to be collected and triaged. Success was measured based on evidence that yielded a DNA profile impactful to the case. Impactful samples were defined as those that were Combined DNA Index System (CODIS) eligible or may generate an investigative lead. The number of samples a customer may request for testing, for each testing round, is limited based on offense type. Providing data on the evidence types that are most likely to yield impactful results can assist the customers with sample selection and triage.

At the DFS, Fired Cartridge Casings (FCCs) are an evidence type that are commonly encountered on homicide crime scenes and collected for DNA testing. Examining the success rates of FCCs to include casings processed as grouped FCCs (8% success rate) as well as non-grouped FCCs (15% success rate) versus other evidentiary types may greatly assist law enforcement when choosing which probative evidence items to prioritize for testing. Choosing the best evidence to test is imperative for these public safety priority cases that do not have a suspect to yield DNA results for CODIS entry and investigative lead purposes.

Additional sample types examined included those typically encountered at property crime scenes. Property crime evidentiary types yielding the lowest success rates included window, household, and door swabs (around 20%). The highest success rates were obtained from bottles, firearms, and wallet-purse swabs (around 50%). The number of evidence items permitted for testing during each round of testing is further limited for property crimes. Choosing the appropriate evidence to test may eliminate the need for additional rounds of testing.

The results of the success rate analyses were presented to DFS customers at a symposium to ensure effective distribution and communication of the data as well as to resolve any questions. At crime scenes, investigators and technicians collecting evidence may also utilize this data. This approach to evaluating the success rate of evidence testing and communicating it to customers can be followed in other forensic laboratories facing resource limitations.

B24 MixMaSTR: A Software Package for Designing and Interpreting Forensic DNA Validation Studies

Sarah Riman, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Hari Iyer, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Peter M. Vallone, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Sarra Amira Chouder, MSc, National Institute of Standards and Technology, Rockville, MD; Edgar Robitaille, Johns Hopkins University, Baltimore, MD; Benjamin Long, BBA, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will gain valuable insight into an open-source and easy-to-use software package, MixMaSTR, that will support the community of forensic practitioners with their DNA validation studies.

Impact Statement: Forensic practitioners face the challenges of designing validation experiments, post-processing, analyzing, and understanding the validation data. The field lacks an open-source software that can assist in these tasks. MixMaSTR, a standalone and easy-to-use application with a graphical user interface, will help practitioners automate the design and interpretation of validation experiments without having to be experts in programming languages or statistics.

Abstract Text: Protocols implemented by forensic laboratories to analyze casework samples must be assessed for performance by validation studies. These studies typically utilize DNA samples of known origin (e.g., staff samples) prepared to reasonably represent the range of sample types routinely accepted and tested by a laboratory. Validation is not a one-time process; laboratories revalidate their methods when changes or upgrades are made to their workflows. As a result, forensic practitioners face the challenges of conducting validation studies, which require significant time and resources.

Here we present the development of MixMaSTR, a standalone, open-source, and easy-to-use application intended to facilitate the design of validation experiments and the interpretation and visualization of the resulting data. In its current form, MixMaSTR includes features that assist practitioners in planning and designing their experiments, prior to data generation and interpretation. MixMaSTR allows users to load their ground truth single-source Short Tandem Repeat (STR) profiles, which are then used to generate all possible mixture genotype combinations based on the specified number of contributors. The software calculates various metrics of interest for each mixture combination, such as allele sharing ratio, instances of rare alleles, adjacent alleles with a 1-base pair difference, and homozygote genotypes. Using statistical theory of experimental design and considering the laboratory's available resources, MixMaSTR generates candidate experimental plans based on user specifications to ensure reasonable coverage of the factor space. The software also provides an efficient strategy to calculate how much of each contributor's DNA is required to make the desired concentration and mixture ratios. PROVEDIt profiles and in-house datasets available in the National Institute of Standards and Technology (NIST) Applied Genetics Group are being used to test the software. They will be shared with collaborative forensic laboratories for usability, relevance, and accuracy feedback before being publicly available. To enhance accessibility, the tool will be accompanied by comprehensive documentation, including installation instructions and step-by-step tutorials demonstrating its use.

B25 Validation of the ForenSeq Kintelligence Kit on the MiSeq FGx for Investigative Genetic Genealogy at Marshall University Forensic Science Center

Tara Knoblach, BS, Marshall University Forensic Science Center, Huntington, WV; Emma A. Katzmann, CLS, QIAGEN, Rochester, MN; Eric Miller, MS, Marshall University Forensic Science Center, Huntington, WV; Laura J. Kuyper, MS, Marshall University Forensic Science Center, Huntington, WV; Cassandra R. Taylor, MS, QIAGEN, Minden, ND; Chelsea R. Garza, PharmD, Marshall University Forensic Science Center, Huntington, WV*

Learning Objectives: This presentation addresses the validation of the ForenSeq Kintelligence Kit on the MiSeq FGx at Marshall University Forensic Science Center (MUFSC). It will provide an overview of the purpose, process and methods, troubleshooting, results, and future applications possible with this technology and applications for Investigative Genetic Genealogy (IGG).

Impact Statement: This presentation will enhance the forensic community by outlining the validation process of the ForenSeq Kintelligence Kit on the MiSeq FGx, offering practical insights for laboratories planning similar implementations. It will also highlight how this system can expand investigative capabilities through IGG.

Abstract Text: As new DNA technologies emerge, forensic laboratories must adapt to increase their testing capabilities. IGG is a growing application that involves sequencing DNA and searching the obtained profile against public DNA databases to identify relatives. The MiSeq FGx system is a sequencing instrument acquired by MUFSC in pursuit of expanding our IGG testing abilities. One kit compatible with this instrument is the ForenSeq Kintelligence Kit, which targets 10,230 Single Nucleotide Polymorphisms (SNPs) using next generation sequencing. MUFSC, along with contributors from QIAGEN, performed a validation of this kit on the MiSeq FGx. This project will address the work involved in this validation, highlighting the troubleshooting process and insights gained throughout.

Validating this technology expands MUFSC's IGG testing capabilities by allowing samples to be processed, extracted, sequenced, and searched against databases entirely in-house. Along with this initiative, MUFSC also partners with genetic genealogists to create family trees and identify potential relatives. The ability to sequence internally will cut down on processing time and avoid the tedious out-sourcing step previously utilized by employing IGG directly at MUFSC.

Key parameters were examined during this validation, such as control performance, precision and accuracy, sensitivity and stochastic thresholds, mixture interpretation, contamination and artifacts, drop-out, mock casework samples, and sample multiplexing. This was accomplished by testing a total of 33 samples of various types, including amplification and sequencing positives, mock casework samples from MUFSC (bone, blood, saliva, and wear DNA), and negative controls. The first steps of this project included amplifying target SNPs in the samples, purifying them with magnetic beads, and then amplifying and purifying them again. Samples were then pooled together before undergoing a denature and dilution step. A singular pool (3 samples) was run at a time on the MiSeq FGx, and 11 pools were sequenced. Our results demonstrate that successful data can be obtained from a variety of sample types at a multitude of concentrations using the MiSeq FGx. Other findings indicate the instrument accurately detects mixtures and low-level contamination, and can also be used to infer ancestry and phenotype from certain samples. These results are crucial in confirming that the MiSeq FGx system provides accurate results for IGG testing.

The ability to sequence DNA samples directly at MUFSC is an important next step in advancing the laboratory's IGG capabilities. Currently, MUFSC has several samples of unidentified human remains awaiting testing. We can now sequence these samples on-site, allowing us to provide identifications to loved ones more quickly. This technology also supports criminal casework by providing faster investigative leads. Additional technologies are now ready for integration into the laboratory as well. MUFSC is in line for validation of a mitochondrial DNA testing kit on the MiSeq FGx, and we hope to expand testing with the ForenSeq MainstAY kit, which will sequence STR loci. This validation marks a pivotal advancement for MUFSC as we step into a new era in forensic science, serving as a leading example of the possibilities gained with this instrument.

B26 A Quantitative Analysis of 12 Cannabinoids From Cannabis Samples Using UPLC-UV-MS

Fiza M. Tajdin, BS, Sam Houston State University, Huntsville, TX; Britni Skillman, PhD, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about the capabilities of Ultra-high-Performance Liquid Chromatography-Ultraviolet spectroscopy-Mass Spectrometry (UPLC-UV-MS) instrumentation for the qualitative and quantitative analysis of cannabinoids from cannabis samples. The audience will learn about the advantages of combining UV and MS detection for quantitation and enhanced compound identification. Attendees will gain insight into the development and validation of a rapid and reliable UPLC-UV-MS method for the analysis of cannabinoids from cannabis samples.

Impact Statement: This presentation will impact the forensic science community by providing a validated UPLC-UV-MS method that offers a rapid approach for the quantification of cannabinoids from cannabis extracts to address the federal legal requirements for the differentiation of hemp and marijuana. This method has practical applications in both forensic laboratories for the analysis of suspected marijuana casework and hemp compliance testing for quality assurance of cannabinoid content in commercial hemp samples.

Abstract Text: The 2018 Agriculture Improvement Act introduced a legal distinction between hemp and marijuana by defining hemp as containing no more than 0.3% Δ^9-Tetrahydrocannabinol (Δ^9-THC) on a dry weight basis, whereas cannabis exceeding the threshold is classified as marijuana. This distinction necessitated the development of sensitive and selective analytical methods to qualitatively and quantitatively assess the total Δ^9-THC content, which includes both Δ^9-THC and Δ^9-Tetrahydrocannabinolic Acid (Δ^9-THCA). Additionally, the legalization of hemp has contributed to an unregulated cannabis industry in which many commercial cannabis samples are frequently mislabeled. Therefore, there is a need to develop a reliable method for the quantification of cannabinoids present in cannabis plant material. The primary hypothesis of this study is that UPLC-UV-MS instrumentation will provide a rapid approach to identify and quantify 12 cannabinoids that may be present in cannabis samples to assist the seized drug community and cannabis industry with the differentiation of hemp and marijuana.

A Waters Acquity UPLC system coupled with a Photodiode Array (PDA) detector and a single Quadrupole (QDa) mass spectrometer was used in this study for the separation, identification, and quantification of cannabinoids found in cannabis samples. The target cannabinoids used for analyses included: Δ^9-THC, Cannabidiol (CBD), Δ^9-THCA, Cannabidiolic Acid (CBDA), Cannabinol (CBN), Cannabichromene (CBC), Cannabigerol (CBG), Cannabicyclol (CBL), Cannabicitran (CBT), Δ^8-Tetrahydrocannabinol (Δ^8-THC), exo-Tetrahydrocannabinol (exo-THC), and (6aR, 9S)-Δ^{10}-tetrahydrocannabinol ((6aR, 9S)-Δ^{10}-THC). Chromatographic separation was performed using an Poroshell 120 EC-C18 column with a gradient elution involving 0.1% formic acid in water and acetonitrile. The PDA acquired data from the 190-700 nm range, with 220 nm selected as the quantitative wavelength due to its optimal absorbance for both acidic and neutral cannabinoids. The QDa was operated with cone voltages ranging from 5 to 35 V in 5 V increments, and a scan range of *m/z* 40–400. Method validation for the developed quantitative method was conducted with guidance from the American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 036, which assessed the following parameters: calibration model linearity, sensitivity, precision (repeatability and reproducibility), accuracy/bias, matrix effects, and carryover. The method was subsequently applied to the analysis of 15 authentic smokable hemp samples to assess its effectiveness in differentiating legal hemp and illicit marijuana.

The validated UPLC-UV-MS method provided a rapid and reliable quantitative approach for differentiating hemp and marijuana. The optimized chromatographic method provided acceptable separation of the target cannabinoids within an 11-minute method, making it suitable for high-throughput applications in forensic laboratories. Of the 15 smokable hemp samples, 9 were determined to contain more than 0.3% total Δ^9-THC content, indicating these hemp samples should be classified as marijuana. Δ^8-THC was identified and quantified in 1 sample, demonstrating the ability to distinguish between Δ^9-THC and Δ^8-THC isomers. The MS detection also enabled the identification of cannabinoids beyond the initial scope of testing through the detection of their protonated molecules, which reduces the risk of compound misidentification. The integration of UV and MS detection in this method supports both reliable quantification and confident compound identification, providing a robust analytical tool for regulatory and forensic applications.

B28 An Analysis of Fentanyl Analogs in Multi-Component Drug Mixtures Using Surface-Enhanced Raman Spectroscopy

Kristen Jerich, BSc, Florida International University, Miami, FL; Bruce R. McCord, PhD, Florida International University, Miami, FL*

Learning Objectives: This study will provide insight into the application of a Surface-Enhanced Raman Spectroscopy (SERS) method using Gold/Silver (Au/Ag) nanoparticles for use in seized drug analysis, focusing on opioids, fentanyl, and fentanyl analogs. The results will include differentiation between 14 fentanyl analogs using SERS and Density Functional Theory (DFT) calculations as well as an analysis of these compounds as mixtures with other drugs and excipients.

Impact Statement: The results show the application of rapid SERS analysis of fentanyl analogs as pure compounds and in mixtures. This method provides a highly sensitive screening approach capable of detecting trace levels of fentanyl analogs and other opioids, permitting rapid in-field detection of unknown compounds.

Abstract Text: The opioid crisis in the United States led to a significant rise in drug-related fatalities over the past decade. In 2024, approximately 80,000 individuals died from drug overdoses, with 60% of these deaths attributed to synthetic opioids, primarily fentanyl and its analogs.[1] Due to its high potency, fentanyl proved lethal at trace levels, underscoring the need for rapid and sensitive detection in complex mixtures and field settings. Fentanyl analogs, which are chemically modified derivatives of the core 4-anilidopiperidine structure, posed additional challenges due to their structural diversity and similar pharmacological effects.

This study utilized SERS to rapidly detect and differentiate fentanyl and its analogs, offering improved sensitivity over conventional Raman spectroscopy. SERS analyses were conducted using hand-held Raman spectrometers, demonstrating their applicability for in-field screening. While prior studies have applied SERS to analyze simple drug mixtures using paper-based and nanosphere-based substrates, in this study we have expanded this approach by examining complex mixtures containing three or more compounds using colloidal gold and silver nanostars.[2-5] These nanostars provide signal enhancement of up to seven orders of magnitude and enable detection of analytes at concentrations as low as 1 ng/mL. Au/Ag nanostars were synthesized and used as enhancing substrates to improve signal intensity and spectral resolution for fentanyl analogs and other scheduled drugs. Aggregating salts were added to facilitate the clustering of analytes with the nanoparticles, promoting greater Raman signal enhancement through localized surface plasmon resonance.

To assign molecular features and support spectral interpretation, DFT calculations were integrated into the workflow. These simulations predict vibrational modes of fentanyl analogs and clarify which regions of the molecule contributed to the observed spectra. The combination of SERS with DFT modeling improved specificity, especially in cases where analogs shared similar core structures or appeared in complex mixtures with other scheduled drugs or adulterants.

A spectral library was successfully developed and computationally supported containing SERS profiles of fentanyl, multiple fentanyl analogs, and commonly encountered adulterants and scheduled substances. This library served as the basis for algorithm development aimed at the detection, differentiation, and quantification of fentanyl analogs in multi-component drug mixtures.

The study confirmed the hypothesis that fentanyl analogs could be detected, even in multi-component drug mixtures, using SERS enhanced by Au/Ag nanoparticles. This methodology provided provides a useful screening technique for forensic, clinical, and field-based drug analysis.

B29 A Cannabis Flower Potency Analysis by Using Liquid Chromatography/Triple Quadrupole/Mass Spectrometry

Na Liu, PhD, Western New England University, Springfield, MA; Liguo Song, PhD, Western Illinois University, Macomb, IL*

Learning Objectives: After attending this presentation, participants will gain an understanding of the key parameters of Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS) for the efficient quantitation of 18 cannabinoids. The presentation will also cover method validation and sample preparation procedures for cannabis flower analysis.

Impact Statement: This study will benefit the forensic science community by providing a robust MS method for the analysis of cannabis flower potency. The instrument employed is commonly available in forensic laboratories, enabling the development of an effective and accessible method for quantifying cannabinoids in cannabis products.

Abstract Text: The Agriculture Improvement Act of 2018, commonly known as 2018 farm bill, legalized the production of hemp containing less than 0.3% (w/w) Δ^9-Tetrahydrocannabinol (THC). This legislation sparked a surge in hemp production across the market. As a result, there is a growing demand for accurate potency testing of hemp-based products to ensure their quality and safety.

An LC/Electron Spray Ionization (ESI) QqQ/MS method was developed to effectively identify and quantify 18 cannabinoids in cannabis flower. Mass spectrometric analysis was performed using Multiple Reaction Monitoring (MRM). Special attention was given to achieving complete baseline separation by LC for structural isomers such as Δ^8- and Δ^9- THC. The quantification method will be validated using neat commercial standards in accordance with ISO 17025 guidelines. The Limit Of Quantitation (LOQ) is targeted to reach 10 ng/mL. Potency analysis of cannabis flower samples will be conducted and supported by standard quality control materials.

Hemp potency analysis has been reported by using LC/Diode Array Detector (DAD), but usually with higher LOQ due to the instrument limitation.[1-5] Recent research showed quantification of cannabinoids in edibles, drinks, oil, etc. using Quadrupole Time-Of-Flight (QTOF) MS.[6,7] The objective of this study is to find an effective quantification method for cannabis flower using QqQ/MS.

B30 The Development of a Validation and Implementation Package for the Quantification of Several Drugs by LC/MS/MS

Meghan G. Appley, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Sarah A. Shuda, MS, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will have an understanding of a validated and implementable Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method for the quantification of a range of forensically relevant drugs.

Impact Statement: This presentation will impact the forensic science community by providing a validation package for the quantification of wide range of compounds that can be implemented for drug analysis in public health and public safety sectors.

Abstract Text: The composition of street drug products across the United States is constantly evolving and tracking these changes are crucial. It is not only vital to identify the various components within drug products (i.e., qualitative analysis), but also to monitor changes in concentration of these compounds (i.e., quantitative analysis) especially in the event of a mass overdose. To produce quantitative information, validated methods for a wide range of compounds are essential. The aim of this project was to develop a single validated quantitative method for numerous relevant compounds using LC/MS/MS.

Public safety and public health agencies were consulted to identify a range of compounds to include in the method scope. The target analytes identified comprised of traditional illicit drugs (e.g., methamphetamine, heroin, and cocaine), cutting agents (e.g., acetaminophen, caffeine, and tetracaine), fentanyl-related compounds (e.g., fentanyl, 4-ANPP, and phenethyl 4-ANPP), and emerging compounds of concern (e.g., BTMPS and nitazenes). A quantification method using LC/MS/MS was developed by optimizing the LC flow gradient, identifying ion transitions and retention times for each compound in the panel, and identifying the analytical measurement range.

Since quantification is usually used for toxicology samples, additional considerations are needed to allow for the analysis of drug products. Sample preparation protocols were designed such that samples received from public health and safety partners by the Rapid Drug Analysis and Research (RaDAR) Program at the National Institute of Standards and Technology could be analyzed by this method. Sample preparation development included determination of appropriate dilutions, assessment of filtering to remove unwanted particulates, and solvent selection.

After the sample preparation and instrument method were optimized, the method was validated. Method validation included assessing the Limits Of Detection (LOD), Lower and Upper Limits Of Quantification (LLOQ and ULOQ), accuracy, precision (both between and within runs), carryover, ion suppression, interference, and the stability of samples both under storage conditions and on the autosampler. Validation was successfully completed for all compounds in the panel. The LLOQ for all of the compounds were determined to be at least 0.1% by weight. A validation and implementation package, including method parameters, a standard operating procedure, and an excel template for compiling validation data, was created so that other laboratories can repeat the validation process and quickly bring the capability online.

Finally, several samples received from multiple collaborators from across the United States were analyzed using previously established qualitative methods followed by the quantitative method developed here. These results were used to track trends within the drug supply.[1]

The result of this project was the production of a validated quantitative method that can be used in combination with already established qualitative methods by public health and public safety entities to perform comprehensive drug checking and trend monitoring.

B31 Drug Profiling in Marion County, Indiana, Using Advanced Statistical Methods and Chemometrics Based on Components Detected by Gas Chromatography/Mass Spectrometry

Natalie N. Holmes, BS, Indiana University Indianapolis, Indianapolis, IN; Philip Brandyberry, MSFS, Indianapolis Marion County Forensic Services Agencey, Indianapolis, IN; John V. Goodpaster, PhD, PhD, Indiana University Indianapolis, Indianapolis, IN*

Learning Objectives: Attendees will be informed regarding: advanced statistical methods and chemometrics were used to compare and classify forensic drug samples based upon active ingredients, adulterants, and diluents as detected by Gas Chromatograph/Mass Spectrometry (GC/MS); the traceability of drug samples using adulterants and diluents as detected by GC/MS; and how advanced statistical methods could be used in future applications, related to drugs or other disciplines.

Impact Statement: Different drug samples (N=135) from the city of Indianapolis over a six-month period were associated with each other using adulterants and diluents along with the drug(s) of abuse. Collaboration with a community forensic lab allowed for "real-time" samples that provided timely, relevant information about the current drug climate. If the amount and concentration of the adulterants and diluents along with any illicit drugs present are consistent between samples and their similarity can be shown using advanced statistical techniques, then this has the potential to be presented as hard scientific evidence in a large drug case.

Abstract Text: GC/MS is often considered to be the "gold standard" in forensic drug laboratories. Forensic labs primarily focus on detecting the most abundant and most illegal substance in an exhibit; this is because the justice system only cares about illicit substances found to press charges. Because of the end goal and their never-ending casework, the other non-illegal substances in these exhibits are not examined. However, it may be possible to correlate various exhibits with one another based on their chemical composition. Adulterants are substances that are added to street drugs that mimic the feeling given by the primary drug desired (such as caffeine being present in a methamphetamine or cocaine exhibit). Diluents do not mimic the activity of the illicit substance present but rather simply "bulk up" the product so that it appears that there is more present than there is. Both types of substances help drug dealers make more money for less actual product (the illicit drug).

At times, investigators have been able to trace the drug sample from the user back to the dealer or sometimes even further back in the drug chain to the manufacturer or shipment it originated from. However, it can sometimes be difficult to charge the manufacturer or any individual further back in the drug chain because the evidence against them is often circumstantial and may rely on witness accounts. If the amount and concentration of the adulterants and diluents along with any illicit drugs present are consistent between these samples and their similarity can be shown using advanced statistical techniques, then it has the potential to be presented as hard scientific evidence in a large drug case. Scientific evidence is far more reliable than eye-witness accounts and would help to alleviate stress that witnesses can feel prior to providing testimony in court.

Drug samples were obtained at random from the Indianapolis Marion County Forensic Services Agency (IMCFSA) and analyzed for similarity. After their analysis, IMCFSA placed the sample GC/MS vials under a heat lamp and dried them down so that a residue remained in the vial and could be transported to our lab. Methanol was added to the GC/MS vials and vortexed for 30 seconds before being analyzed. Both split and splitless modes of a method inspired by IMCFSA's GC/MS method were used to analyze the samples due to variation in sample concentrations.

Of the 135 samples analyzed, fentanyl, fentanyl analogs, cocaine, and heroin were among the most identified illicit drugs. Additionally, newly emerged drugs such as BTMPS were identified .[1] Acetaminophen and caffeine were the most common adulterants and diluents identified. Notable correlations between drugs seen in the same samples include acetyl codeine and heroin, o-6-monoacetylmorphine and morphine, norfentanyl and 4-ANPP, and carfentanil and clozapine. There was little to no correlation seen between acetaminophen or caffeine and any other compounds.

B32 Evaluating Extraction Techniques for Mushrooms in Chocolate to Avoid Potential 4-Acetoxy-N,N-Dimethyltryptamine Hydrolysis

Naria A. Ford-Thompson, MSFS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA; Elizabeth Shields, Waynesburg University, Pittsburgh, PA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of some concerns and analytical challenges regarding mushroom chocolate sample analysis. The comparison of two extraction techniques (an acid-base extraction utilizing chloroform and a Quick, Easy, Cheap, Effective, Rugged, and Safe [QuEChERS[technique utilizing dispersive solid phase extraction) will be presented with focus on preventing the conversion of the synthetic psilocin derivative 4-acetoxy-N,N-Dimethyltryptamine (4-acetoxy-DMT)to psilocin.

Impact Statement: This presentation will impact the forensic community by highlighting an extraction technique that can be used to isolate psilocin from suspected mushroom chocolate samples without leading to the conversion of 4-acetoxy-DMT. Overall, this will lead to increased confidence in extractions.

Abstract Text: Increasingly encountered by Controlled Substance analysts are edible items containing a variety of novel psychoactive substances. These items are often branded and sold as "legal loopholes" and have led to analytical challenges due to their complex matrices.

A common technique for suspected mushroom analysis is an acid-base extraction that can be applied to edible items. Recent concerns have been raised regarding the potential of acid extractions inadvertently converting synthetic psilocin derivatives, such as 4-acetoxy-DMT to psilocin.[1] This conversion could misidentify and inaccurately confirm a federally scheduled compound instead of non-scheduled synthetic compound.

Procedures from forensic laboratories were consulted to find other extraction methods for mushroom samples. QuEChERS extractions are being utilized for samples with complex matrices; however, no references were found indicating whether those techniques lead to the conversion of synthetic derivatives to psilocin.[2] To address this, two extraction techniques were concurrently studied on chocolate samples made in the laboratory with known concentrations of psilocin, psilocybin, 4-acetoxy-DMT, and mixtures of those standards. The methods compared were an acid-base extraction utilizing acetic acid, sodium bicarbonate and, chloroform[3] and a QuEChERS technique utilizing EN method extraction salts and AOAC dispersive solid phase extraction kits.[2,3] All extracts were run on a dual gas chromatography mass spectrometer and flame ionization detector instrument for qualitative analysis.

Early results show that psilocybin was not detected in any of the psilocybin chocolate samples evaluated with either extraction procedure as expected. Psilocin was not detected either, though it should be noted that the chocolate samples were prepared at temperatures to prevent initial conversion from psilocybin to psilocin. Out of the psilocin chocolate samples evaluated with both extraction procedures, psilocin was detected in all occurrences and confirmed in all but one sample. 4-acetoxy-DMT was detected and confirmed in all 4-acetoxy-DMT chocolate samples extracted with both methods; however, in those extracted with the QuEChERS method, psilocin was also detected.[2,3] In the mixture samples, all intended compounds were detected in both extraction procedures apart from psilocybin, which was again not detected in any of its intended samples.[2,3] However, psilocin was detected in the 4-acetoxy-DMT and psilocybin mixture samples when the QuEChERS extraction method was performed.[2]

Both the acid-base and the QuEChERS extractions produced consistent results and were successful in detecting and confirming psilocin thus far.[2,3] The QuEChERS technique is an appropriate extraction technique for complex matrices but was not as reliable as the acid-base extraction for samples containing 4-acetoxy-N,N-dimethyltryptamine, a synthetic derivative of psilocin.

B33 Investigating the Stability and Degradation of Psilocybin and Psilocin in Mushroom Gummies: Implications for Forensic Analysis

Alyssa Ricca, BS, Cedar Crest College, North Middletown, NJ; Marianne Staretz, PhD, Ceadr Crest College, Allentown, PA; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA; Mia Bercier, MSFS, Cedar Crest College , Birmingham, AL*

Learning Objectives: Attendees will learn about the stability of psilocybin and psilocin in gummies, with emphasis on how storage conditions impact analyte integrity over time. The presentation will highlight the use of a validated Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method, including calibration curve development, repeatability and reproducibility studies, and determination of Limits Of Detection and Quantitation (LOD and LOQ). Additionally, it will cover the evaluation of extraction efficiency and drug homogeneity within the gummies. These findings will be discussed in a forensic context focusing on how they affect the interpretation of evidence involving psychedelic gummies.

Impact Statement: This presentation will impact the forensic science community by providing a validated LC/MS/MS method and a comparative evaluation of multiple extraction techniques that can be used to establish standardized analytical protocols for the examination of mushroom gummies. By analyzing the stability of psilocybin and psilocin over time under various storage conditions, this research will improve forensic scientists' ability to assess how concentration changes post-manufacture. Additionally, this research determines the potential for psilocybin to convert to psilocin within a gummy matrix, offering critical insight for accurate interpretation in forensic casework involving psychedelic gummies.

Abstract Text: After attending this presentation, attendees will understand how psilocybin and psilocin concentrations change over time under different storage conditions in a gummy matrix, how homogeneously the drugs are distributed within the gummy, and how validated LC/MS/MS methods can be used to analyze these compounds in forensic casework. This presentation will impact the forensic science community by providing a validated analytical method that will aid in accurately interpreting mushroom gummy results by accounting for storage conditions, time, and the potential conversion of psilocybin to psilocin within the gummy matrix.

Psychedelic mushrooms are increasingly being processed into edible forms, such as gummies, for recreational and self-medication purposes. This shift presents new challenges in forensic analysis due to instability of psilocybin and psilocin as well as the complexity of edible matrices. The hypothesis of this study is that storage conditions affect the degradation and conversion of these compounds, which may impact quantitation accuracy and evidence interpretation.

An LC/MS/MS method was developed and validated for the quantitation of psilocybin and psilocin in mushroom gummies. Deuterated internal standards were spiked into all standards and samples prior to extraction to account for matrix effects and variability. Method validation included calibration curve construction (R^2 = 0.9763 for psilocybin and R^2 = 0.9970 for psilocin), determination of LOD and LOQ (LOD = 0.0398 µg/mL and LOQ = 0.1205 µg/mL for psilocybin; LOD = 0.0094 µg/mL and LOQ = 0.0284 µg/mL for psilocin), recovery studies, and stability testing across various storage conditions. Validation also included repeatability and reproducibility studies, with psilocybin's %RSDs below 10% and psilocin's below 17%.

Multiple extraction methods were evaluated, including ceramic bead homogenization, tissue homogenization, and Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS), using various solvents. Ceramic bead homogenization with water provided the best recoveries for both analytes: 83.11% for psilocybin and 94.84% for psilocin. Drug distribution within gummies was assessed to determine homogeneity, with sample %RSDs ranging from 8.37% - 19.41% for psilocybin and 2.61% - 14.29% for psilocin. Stability was assessed by analyzing samples at Day 0, 3, 7, 14, 21, and upcoming 30, 45, and 60-day intervals to track trends in analyte degradation or formation over time.

Stability testing revealed that psilocin concentrations increased relative to Day 0 under all conditions, with refrigerated gummies showing the greatest increase (121.4% on Day 14). Psilocybin gummy concentrations initially decreased and then increased, also peaking under refrigerated conditions (72.2% on Day 7). After reaching peak levels, psilocin and psilocybin concentrations declined under all conditions, generally remaining above their Day 0 concentrations, except in the ambient light condition for psilocin. A small psilocin peak was observed forming in psilocybin gummies supporting a possible *in situ* dephosphorylation reaction within the matrix. Later time points will also be analyzed and presented.

This presentation provides a framework for understanding chemical changes in psychedelic edibles over time and highlights the need for time-sensitive, validated forensic methods to accurately assess seized samples containing psilocybin and psilocin.

B34 Microcrystalline Tests for the Detection of Novel Psychoactive Substances (NPS)

Grace Pavel, Western Carolina University, Cullowhee, NC; Ruby Alley*, Western Carolina University, Cullowhee, NC; Kimiko Ferguson, PhD, Western Carolina University, Cullowhee, NC*

Learning Objectives: Attendees will learn about the utility of microcrystalline tests for the detection of drugs in forensic science. They will specifically become familiar with microcrystalline tests for nitazenes and other emerging NPS and the identification of each drug type by the characteristic shape of the crystal and Fourier-Transform Infrared (FTIR) spectra produced.

Impact Statement: The forensic science community will become competent in the application of microcrystalline tests for the presence of nitazenes and other emerging NPS. As a result, forensic practitioners will have more microcrystalline test tools in their tool box for the analysis of these emerging NPS. The results of these tests increase the information available to the forensic science community about characteristic crystal shapes produced by microcrystalline tests for these emerging NPS.

Abstract Text: Forensic drug analysis supports law enforcement authorities through the application of chemical analytical techniques to assist in identifying drugs. The microcrytalline test is a chemical test resulting in a microcrystal that can be observed under a Polarizing Light Microscope (PLM).[1,2] According to the Center for Forensic Science Research and Education (CFSRE), trends from Q1 2024 to Q2 2025, metonitazene, carfentanil, N-pyrrolidino Protonitazene, and protonitazene were the most commonly identified.[3] In Q2 2025, there were approximately 38% benzodiazepines, 35% synthetic cannabinoids, 19% opioids, and 8% stimulants & hallucinogens identified.[3] Hence, the microcrystalline test study is focused on the classes benzodiazepines (bromazolam, phenazolam), synthetic cannabinoids (MDMB-Inaca, MDMB-4en-PINACA), and opioids (protonitazene, isotonitazene, metonitazene).

It was hypothesized that each drug standard would produce its own characteristic shape of microcrystal, and distinctive FTIR spectra. A drop of each of the reagents gold chloride, platinic chloride, gold bromide, platinic bromide, mercuric chloride, and mercuric iodide were evaluated with each of the drug chemical reference standard prepared at 1 mg/mL concentration. Microcrystal formation time, shape, and characteristics were observed under a PLM and documented. The test results show distinguishing crystals, with gold-derived reagents forming distinct microcrystals with most drug standards studied. Additionally, features of FTIR spectra characteristic of the microcrystal formed were observed for each drug standard. In conclusion, the microcrystalline tests utilized, particularly those from gold-derived reagents, were useful for the detection of NPS.

B35 The Development and Validation of a Rapid Direct Analysis in Real Time-Triple Quadrupole/Mass Spectrometry (DART-QqQ/MS) Method for Screening Nitazene Analogs

Nicholas Khorozov, MS, Center for Forensic Science Research & Education, Willow Grove, PA; Alex J. Krotulski, PhD, Center for Forensic Science Research & Education, Horsham, PA; Barry K. Logan, PhD, Center for Forensic Science Research & Education, Horsham, PA; Joshua S. DeBord, PhD, Center for Forensic Science Research & Education, Horsham, PA*

Learning Objectives: The objective of this presentation is to familiarize the audience with qualitative DART-QqQ/MS method development and validation. Attendees can expect to learn how DART-QqQ/MS can be effectively optimized for the highly potent opioid sub-class of nitazenes. This presentation is angled toward forensic scientists who are interested in learning more about chromatography-free alternatives for drug screening or confirmation.

Impact Statement: This work will positively affect the forensic science community by demonstrating a quick and reliable method for the identification of nitazene analogs. The application of DART-QqQ/MS to nitazenes highlights the growing utility of ambient ionization techniques in forensic chemistry. By enabling compound detection in a matter of seconds, methods can be integrated into routine laboratory workflows to increase analytical throughout and to facilitate the detection of novel psychoactive compounds not typically identified in standard drug screens.

Abstract Text: The rapid identification of novel synthetic opioids, including nitazene analogs, fentanyl analogs, and orphine analogs, is of growing interest in forensic chemistry. Their high potency and implication in polysubstance scenarios have led to a large number of fatal and non-fatal overdoses in the United States. The structural diversity of novel opioids, especially nitazene analogs, complicates detection and identification, with established chromatographic techniques for analysis of seized drug materials often producing false positives or inaccurate identifications. Failure to identify the presence of these substances in forensic and medicolegal death investigations can be problematic and impact case outcomes. There is a growing need for rapid and reliable screening methods that can keep pace with evolving drug trends. DART-QqQ/MS offers the ability to analyze samples with minimal preparation within seconds, making it a valuable alternative for the detection of nitazenes in forensic chemistry samples.

Our laboratory developed a DART-QqQ/MS method for the rapid screening of various nitazene analogs, including Etonitazene, N-pyrrolidino Etonitazene, N-piperidinyl Etonitazene, Metonitazene, N-pyrrolidino Metonitazene, N-desethyl Metonitazene, Protonitazene, N-piperidinyl Protonitazene, N-desethyl Protonitazene, N-pyrrolidino Protonitazene, Butonitazene, N-pyrrolidino Butonitazene, N-piperidinyl Butonitazene, and N-desethyl Butonitazene. Isotonitazene-d7 was used as a universal internal standard. The instrument used was a Bruker EVOQ DART-TQ+ mass spectrometer. The development of the DART method involved the optimization of instrumental parameters such as ionization gas temperature, sampling mode, cone temperature, and grid voltage. Following optimization of instrumental parameters, the method was validated to measure sensitivity, specificity, and environmental effects.

The Limit Of Detection (LOD) for nitazene analogs in methanol was 25 ng/mL. Though some analytes could be detected at lower levels, this concentration was set as the LOD for all analytes. An interference study demonstrated that common compounds found in drug testing such as fentanyl, methamphetamine, and cocaine did not produce an instrumental response above the limit of detection. Common adulterants such as caffeine, lidocaine, and diphenhydramine additionally did not interfere with nitazene detection. To evaluate environmental effects, solvents including methanol, acetone, chloroform, and hexane were used as diluents. It was found that all four solvents, when spiked with nitazene test mix, did not significantly differ in response.

The validated method was applied to authentic drug samples obtained from collaborators of the Center for Forensic Science Research & Education (CFSRE). Four samples previously confirmed to contain Metonitazene (n=2), Protonitazene (n=1), N-pyrrolidino Metonitazene (n=2), and N-pyrrolidino Protonitazene (n=2) by qualitative Gas Chromatograph/Mass Spectrometry (GC/MS) and Liquid Chromatography/Quadrupole Time-Of-Flight/Mass Spectrometry (LC/QTOF/MS) methods were consistent with results from the validated DART-QqQ/MS method. These findings demonstrate that rapid, chromatography-free analytical methods can be effectively and reliably applied to drug material suspected to contain nitazene analogs.

B36 Development and Validation of a GC-MS Method for the Quantitation of 23 Different Acidic and Neutral Cannabinoids

Amal Ali, MA, University of Mississippi, Oxford, MS; Mostafa Elhendawy, PhD, University of Mississippi, Oxford, MS; Mohamed Radwan, PhD, University of Mississippi, Oxford, MS; Amira Wanas, PhD, University of Mississippi, Oxford, MS; Adel A. Marzouk; University of Mississippi, Oxford, MS; Suman Chandra, PhD, University of Mississippi, Oxford, MS; Mahmoud ElSohly, PhD, University of Mississippi, Oxford, MS; Murrell Godfrey, PhD, University of Mississippi, Oxford, MS*

Learning Objectives: By attending this presentation, participants will be able to: describe how derivatization techniques address the challenges of analyzing both acidic and neutral cannabinoids using conventional Gas Chromatograph/Mass Spectrometry (GC/MS) methods; recognize the novelty of the developed method, including: (1) the use of an MS detector instead of the Flame Ionization Detector (FID) commonly reported in previous methods; (2) the implementation of a more polar GC column and how to apply column selection strategies when analyzing complex phytochemical mixtures; and (3) the successful separation of cannabinoid isomers, including newly resolved compounds that have not been reported in earlier studies; and evaluate the suitability and potential applications of this GC/MS method for cannabinoid profiling in research, quality control, and regulatory settings.

Impact Statement: This presentation introduces a time-efficient and cost-effective GC/MS method for the simultaneous separation of 21 acidic and neutral cannabinoids using a shorter and more polar GC column. The method achieves full separation in just 13 minutes, significantly reducing analysis time, column wear, and resource consumption. Enhanced isomer resolution allows for more accurate chemovar differentiation, which is critical for forensic investigations involving cannabis identification and classification. This advancement supports the forensic science community by improving the speed, precision, and affordability of cannabinoid profiling in legal and criminal justice applications.

Abstract Text: *Cannabis sativa* L. is widely utilized for its therapeutic and commercial potential, driven by its diverse phytochemicals such as cannabinoids, terpenes, and flavonoids. Accurate profiling of cannabinoids is essential for chemovar fingerprinting; however, conventional methods often require extensive pre-purification. This study introduces a novel, simple and validated GC-MS method for the simultaneous analysis of 15 neutral and 8 acidic cannabinoids, namely, CBDA, CBDVA, CBNA, CBLA, CBCA, Δ^9-THCVA, Δ^9-THCAA, CBGA, CBDV, CBD, CBV, Δ^9-THCV, CBC, Δ^8-THC, Δ^8- THCV, Δ^9-THC, CBG, CBN, CBT, CBE, 9RΔ^{10}-THC, CBND, and CBNR.

The method showed satisfactory linearity with R2 > 0.995 for all 23 cannabinoids. The method limit of detection (LOD) ranged from 0.01 to 0.025 µg/mL, while the limit of quantitation (LOQ) ranged from 0.025 to 0.05 µg/mL. Method precision was calculated as the % relative standard deviation (% RSD), and the value was ≤ 15%. The developed method is simple, fast, accurate, and sensitive for the quantitation of all 23 cannabinoids TMS derivatives, all eluting within approximately 13 minutes. Finally, the proposed method was successfully applied to the quantitation of the cannabinoids in different cannabis chemovars grown at the University of Mississippi.

B37 The Development of an Optimized Extraction Protocol for Cannabinoids From Cannabis Plant Material

Emma M. Fitzgibbons, MS, Sam Houston State University, Huntsville, TX; Britni Skillman, PhD, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about an optimized extraction protocol for 12 cannabinoids from cannabis plant material. The audience will learn about the performance of five common solvents, two mixing methods for three different time points, and the use of a centrifuge versus allowing samples to settle on cannabinoid recovery. This information will provide attendees with an optimized extraction protocol that can be incorporated into casework to maximize cannabinoid recovery.

Impact Statement: This presentation will impact the forensic science community by providing an optimized method for the extraction of 12 cannabinoids from cannabis plant material, followed by analysis using a validated Ultra-Performance Liquid Chromatography-Photodiode Array-single Quadrupole (UPLC-PDA-QDA) method for identification and quantitation of each cannabinoid. The optimized extraction protocol can be implemented using common laboratory equipment and solvents, increasing its availability to practitioners. Incorporating the optimized extraction protocol can enhance total cannabinoid recovery from cannabis plant material.

Abstract Text: The Agriculture Improvement Act of 2018 defined marijuana as *Cannabis sativa* L. or any derivatives that contain greater than 0.3% Δ^9-Tetrahydrocannabinol (Δ^9-THC) on a dry weight basis, whereas hemp contains no more than 0.3% Δ^9-THC. Due to the classification of marijuana as a Schedule I controlled substance, seized drug analysts must be able to perform both qualitative and quantitative analysis of the total THC content in potential marijuana plant material, which includes Δ^9-THC and its acidic precursor, Tetrahydrocannabinolic acid (THCA). These cannabinoids, along with Cannabidiol (CBD) and its acidic precursor, Cannabidiolic Acid (CBDA), are the main components of hemp and marijuana, which must be extracted from cannabis plant material before analysis. The efficiency of the extraction protocol can impact the total THC extracted and thus, the classification of legal hemp versus illegal marijuana. The central hypothesis of this research is that the extraction of cannabinoids from cannabis plant material can be optimized by altering the solvent, mixing methods and duration, and centrifugation versus sample settling.

A Waters Acquity UPLC-PDA-QDa mass spectrometer with a Poroshell 120 EC-C18 column (100 mm length, 2.1 mm I.D., and 2.7 µm average particle size) was used for the analysis of 12 commonly encountered cannabinoids. The extraction protocol was optimized in three phases based on 50 mg ± 0.5 mg of cannabis plant material, 5 mL of solvent, vortexing for 10 seconds, letting the sample stand for 5 minutes, vortexing for another 10 seconds, filtering through a cotton plugged pipette, and repeating the process with another 5 mL of methanol. The first phase was solvent optimization, where methanol, ethyl acetate, acetonitrile, methanol/chloroform (9:1), methanol/hexane (9:1), and hexane/ethyl acetate (6:4) were used for the extraction of authentic cannabis in triplicate. The second phase assessed the mixing method and duration. The hemp and marijuana samples were vortexed for 10 seconds, either rocked or left to stand for 1, 5, or 10 minutes, then vortexed for another 10 seconds. The third phase focused on the impact of centrifugation versus sample settling. After all phases were completed, a final recovery study was conducted by extracting authentic hemp and marijuana samples three times using the optimized protocol to estimate the extraction efficiency.

The optimized extraction protocol used 5 mL of methanol as the solvent, 10 minutes of rocking between 10 second vortexes, sample settling for 5 minutes, and filtration through a cotton plugged pipette, completed in duplicate. Methanol was chosen as the solvent due to comparable results to other solvents and its miscibility with the mobile phases, avoiding the need for drying down and sample reconstitution. Rocking the sample for 10 minutes resulted in the highest yield of cannabinoids. Centrifugation did not significantly improve extraction efficiency and required additional time and equipment, so sample settling was chosen instead. Sequential extractions of hemp and marijuana plant material revealed 99% recovery for cannabinoids using the optimized extraction protocol. These results demonstrate that the optimized extraction protocol provides a method to maximize cannabinoid recovery from cannabis plant material.

B38 The Identification of Methyl-Substituted Fentanyl Analogs Using Optimized Weighting Within the Inverted Library Search Algorithm (ILSA)

Christany Liggins, BS, Sam Houston State University, Huntsville, MS; Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX; Arun S. Moorthy, PhD, Trent University, Peterborough, Ontario, Canada*

Learning Objectives: After attending this presentation, attendees will have learned about the identification of methyl-substituted fentanyl analogs using optimized weighting within the ILSA, which is used to compare mass spectra within the National Institute of Standards and Technology (NIST) Data Interpretation Tool (DIT). The audience will learn about the advantages of incorporating optimized weighting for the more fragmentation-rich mass spectra within the ILSA for improved identification of methyl-substituted fentanyl analogs. Finally, the audience will learn about the use of an Average Reverse Match Factor (RevMF) scoring threshold to help reduce false positives.

Impact Statement: This presentation will impact the forensic science community by demonstrating the potential for improved fentanyl analog isomer identification using optimized weighing with the ILSA. Optimized weighting shows the potential to enhance the utility of the NIST DIT for rapid presumptive identification of seized drugs, particularly for fentanyl analog isomers.

Abstract Text: As the illicit drug landscape continues to evolve, more rapid and reliable analytical techniques are required to address growing backlogs. One promising solution is Direct Analysis In Real Time-Mass Spectrometry (DART-MS); however, the resulting mass spectra can be challenging to interpret due to a lack of chromatographic separation. The NIST DIT was developed to address this challenge based on the comparison of In-Source Collision-Induced Dissociation (IS-CID) mass spectra at low, medium, and higher activation energies. The NIST DIT utilizes a novel algorithm known as the ILSA to search for partial patterns within a mass spectrum. The ILSA generates two similarity scores, the Fraction of Peak Intensity Explained (FPIE) and RevMF to help users compare mass spectra. The RevMF and FPIE scores currently generated by the ILSA are based on equal weighting of the low, medium, and high activation energy spectra. Unfortunately, the ILSA struggles with the correct identification of isomers. The central hypothesis of this research is that optimizing the weighting of the low, medium, and high activation energy mass spectra will lead to improved identification of methyl-substituted fentanyl analog isomers.

A DART JumpShot ionization source coupled to an Agilent Q-TOF mass spectrometer was used to analyze a series of isobaric methyl-substituted fentanyl analogs. The analogs studied include 4-methyl fentanyl, 4'-methyl fentanyl, butyryl fentanyl, isobutyryl fentanyl, ortho-methyl fentanyl, trans-3-methyl fentanyl, α-methyl fentanyl, and β-methyl fentanyl. Samples were introduced to the DART source using QuickStrips. All analyses were completed in positive ionization mode using helium as the source gas. RStudio was utilized to enable ILSA processing. Query mass spectra were searched against an in-house library consisting of the product ion spectra collected at 0, 30, and 60 eV for each isobaric methyl-substituted fentanyl analog. The spectral search parameters included a target threshold of 1% and an *m/z* tolerance of ±0.005 Da.

In comparison to FPIE, improved performance with RevMF identification was achieved with optimized weighing. A 50:50 weighting of the medium and high energy spectra was identified as the optimal weighting, with each methyl-substituted fentanyl analog being distinguishable except for butyryl fentanyl, isobutyryl fentanyl, and ortho-methyl fentanyl, which are isospectral. Combined with an optimized RevMF scoring threshold of 0.80, the 50:50 optimized weighting reduced false positives compared to the original approach. For example, in the case of a 1:1 mixture containing 4-methyl fentanyl and β-methyl fentanyl, the original RevMF calculation identified 4-methyl fentanyl and β-methyl fentanyl as present, with trans-3-methyl fentanyl and α-methyl fentanyl being false positives. In contrast, the 50:50 optimized weighting RevMF only identified 4-methyl fentanyl, α-methyl fentanyl, and β-methyl fentanyl as present, resulting in a reduced false positive identification. Both methods incorrectly identified α-methyl fentanyl due to its shared R-group substitution location with β-methyl fentanyl. These results suggest that implementing an optimized weighted scoring system could effectively reduce false positives for the identification of isobaric compounds. Overall, this study highlights the potential of optimized weighting with the ILSA to provide enhanced isomer identification with the NIST DIT.

B39 Under the Light: UV/Vis Spectrophotometry as a Tool for Characterizing Designer and Traditional Benzodiazepines in Varying Solvent Systems

Kailee R. Marchand, BS, Sam Houston State University, Huntsville, TX; Cailin Herl, MSFS, Sam Houston State University, Tacoma, WA; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX; Alaina Anderson, MS, HFSC, Houston, TX; James T. Miller, MA, Houston Forensic Science Center, Houston, TX; Mona Colca, BA, Houston Forensic Science Center, Houston, TX*

Learning Objectives: After attending this presentation, attendees will acquire knowledge of the effects pH conditions have on the absorption spectra lambda max (λmax) values of traditional and designer benzodiazepines. The audience will learn about how the λmax values gathered from those Ultraviolet (UV) absorption spectra serve as a characteristic feature of traditional and designer benzodiazepines, and how Ultraviolet/Visible (UV-vis) spectrophotometry can be used for their preliminary identification.

Impact Statement: This presentation will impact the forensic science community by suggesting a fast, cost-effective, and accurate technique for the preliminary characterization of traditional and designer benzodiazepines. The method is based on their distinct absorption spectra and λmax values in varying pH environments, as obtained using UV/Vis spectrophotometry.

Abstract Text: In recent years, benzodiazepines have become increasingly prevalent in forensic casework, with the emergence of designer benzodiazepines requiring further characterization to aid seized drug analysts in their identification. For example, since 2022, the Houston Forensic Science Center (HFSC) has detected 12 benzodiazepines in seized drug evidence, 8 of which were designer. UV-vis spectrophotometry, a common presumptive technique in forensic laboratories, offers a promising approach for the preliminary characterization of both traditional and novel benzodiazepines. In this study, UV-vis spectrophotometry characterized a range of traditional and designer benzodiazepines based on characteristic absorption bands across varying pH conditions.

Six traditional and five designer benzodiazepines were dissolved in sulfuric acid, methanol, phosphate buffer, and sodium hydroxide to achieve solutions with pH values of 0.5, 6, 7.4, and 13, respectively. A 20-ppm stock solution was prepared for each, from which dilutions were performed to create solutions at 16, 12, 8, 4, 2, 1.6, 1.2, 0.8, 0.4, and 0.2 ppm concentrations. The spectra of each solution were collected using a UV-vis spectrophotometer in absorption mode across the wavelength range of 220-340 nm, with a sampling interval of 0.5 nm, a fast scan speed, and single scan mode. All measurements were acquired using a quartz cuvette with a 1 cm optical path length. Following spectral acquisition, the absorption spectra were visualized, and the wavelength of maximum absorbance (λmax) was identified for all benzodiazepines. The absorbance values at λmax were then plotted against the corresponding concentrations to evaluate the linearity of the serial dilutions based on the coefficient of determination ($R2$) value.

In sulfuric acid (pH 0.5), all traditional benzodiazepines demonstrated R2 values above 0.97, with four exceeding 0.99. Similarly, four out of the five designer benzodiazepines had $R2$ values above 0.99, and all exceeded 0.97, indicating strong linearity. In methanol (pH 6), traditional and designer benzodiazepines displayed similar peak shapes and λmax values, suggesting UV-vis spectrophotometry alone may not be sufficient for differentiating them in this solvent. In comparison to sulfuric acid, spectra obtained in methanol exhibited broader and less defined absorption bands, along with shifts in λmax values. Acceptable spectra were obtained from all benzodiazepines in phosphate buffer (pH 7.4), except phenazolam. However, three of the benzodiazepines produced spectra nearly indistinguishable from each other due to overlapping λmax values and similar absorption band characteristics. In sodium hydroxide (pH 13), most benzodiazepines exhibited lower absorbance values and lacked clearly identifiable λmax values. Nonetheless, 4'-chloro deschloroalprazolam, phenazepam, and flubromazepam produced spectra with distinguishable λmax values.

Overall, characteristic spectra were obtained for most designer benzodiazepines in strongly acidic conditions, which could be beneficial to practitioners. Among the 11 benzodiazepines analyzed, 4'-chloro deschloroalprazolam and clonazepam showed the greatest differentiation in methanol, while flubromazepam and diazepam exhibited the most pronounced spectral differences in sodium hydroxide. These results demonstrate that UV-vis spectrophotometry, a fast and cost-effective technique, can be used as a tool for the characterization of traditional and designer benzodiazepines. Its practicality is especially relevant for seized drug analysts seeking to exploit pH-dependent spectral variations for preliminary identification.

B40 Using Dry ATR/FTIR Spectroscopy to Identify 1,4-Butanediol in Alcoholic Beverages

Thomas Spudich, PhD, Southern Illinois University Edwardsville, Belleville, IL; Ethan Nugen, Southern Illinois University Edwardsville, Belleville, IL; Christina Hayes, MNS, St. Louis Metropolitan Police Dept. Crime Laboratory, Saint Louis, MO; Marissa Purfeerst, BS, Southern Illinois University Edwardsville, Belleville, IL*

Learning Objectives: After this presentation, attendees will: be familiar with the Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) technique, be familiar with techniques used to identify adulterants in alcoholic beverages, and understand the advantages of the dry ATR/FTIR technique in general.

Impact Statement: This work shows the added flexibility of using the dry ATR/FTIR technique to identify adulterants. In particular, this presentation shows the ability to identify 1,4-butanediol in about 20 minutes in a variety of samples.

Abstract Text: ATR/FTIR can be used to identify and determine the presence of IR-active molecules. When working with a liquid mixture, a sample can be allowed to dry on a transparent crystal, which allows for IR radiation to traverse the sample, so only the non-volatile material will be analyzed utilizing a technique called Dry ATR/FTIR. The chemical 1,4-butanediol, which is a derivative of GHB, is becoming more prevalent in drug-facilitated crimes, making it a key interest in forensic crime laboratories.

There is currently no standardized method to identify the presence of 1,4-butanediol in alcoholic beverages. Due to the IR-active nature and high viscosity of this chemical, Dry ATR/FTIR can be used to identify 1,4-butanediol from the rest of the alcohol beverage mixture. Samples were made by mixing 1,4-butanediol with alcohol and several different mixers. The concentrations of 1,4-butanediol in these samples were determined in accordance with the common street dosages of GHB, from most to least safe. The spectra produced by these samples were analyzed by utilizing SpectraGryph software to identify the presence of peaks unique to 1,4-butanediol. By using this software with the data from the Dry ATR/FTIR method, the presence of 1,4-butanediol was determined in several alcoholic beverages.

B41 A Headspace Analysis of Reference Grade and Seized Xylazine, 4-ANPP, and Nitazenes

Sadie Olrogg, BS, Florida International University, Pembroke Pines, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL*

Learning Objectives: This poster will provide insight into Volatile Organic Compounds (VOCs) found in the headspace analysis of emerging drugs. A comparative analysis will be shown of illicit drugs analyzed from reference grade and seized samples.

Impact Statement: The results will show the VOCs that can be used for these emerging drugs for canine detection for both reference-grade material as well as adulterated mixtures. These findings are critical for the development of canine training protocols, ensuring reliability across a wide range of drug formulations, and improving interpretation of canine alerts in the field.

Abstract Text: Canine odor detection is a common technique when attempting to locate illicit drugs at ports of entry or in other law enforcement applications. These detection dogs respond when they encounter VOCs specific to the drugs they are trained to detect.[1] To better understand this olfactory process and to help enhance the ability of these canines, VOCs from reference-grade and seized drug samples should be identified from the headspace profile of these illicit drugs.[2-4] The primary method of collecting these VOCs in the field and in the laboratory is to use Solid Phase Microextraction paired with Gas Chromatography/Mass Spectroscopy (SPME-GC/MS). This research utilized a previously optimized method of SPME-GC/MS for the headspace analysis of fentanyl.[3] The experiment starts with a 24-hour equilibration period followed by a 24-hour heated (35°C) extraction and thermal desorption into the GC/MS.

The 2023 National Forensic Laboratory Information Systems (NFLIS) snapshot report and the 2022 Center for Forensic Science Research and Education (CFSRE) trend report listed xylazine, 4- Anilino-N-Phenethylpiperidine (4-ANPP) and benzimidazole opioids (nitazenes) seizures as increasing in prevalence.[5-6] Xylazine is a non-opioid sedative that has recently been added to the illicit drug market as an adulterant frequently present with cocaine, heroin and fentanyl.[7] Above 10% of all fentanyl-related overdoses detected the presence of xylazine.[8] 4-ANPP is a pharmacologically inactive chemical that is a fentanyl precursor used in the synthesis of fentanyl and its analogs.[9] It is frequently detected in tandem with fentanyl or fentanyl analogs due to degradation of the parent molecule or leftover chemicals from synthesis. Finally, benzimidazole opioids, more commonly known as nitazenes, are a group of over twenty benzimidazole opioid compounds that have high potency compared to morphine. The nitazene analogs have a variety of potencies, with some even being 20 times more potent than fentanyl.[10]

This research has identified vapor surrogates such as toluene, for xylazine, 4-ANPP, and several nitazene analogs from reference materials. Seized nitazenes have identified many synthesis materials and byproducts such as quinolone, dimethyl sulfone, acetic acid, and N-N dimethylformamide. Although no single compound has been consistently observed across all nitazenes analyzed, there is a notable overlap between several compounds. These shared byproducts proved valuable insight into potential synthesis pathways/reagents used and can serve as promising candidates for target VOCs for canine detection.

B42 LC/MS and GC/MS Analyses of the Decomposition Products of Fentanyl Using Various Oxidative Processes

Mehdi Moini, PhD, George Mason University, Manassas, VA; Edward Bentil, PhD, George Mason University, Manassas, VA; Brian Eckenrode, PhD, George Mason University, Manassas, VA*

Learning Objectives: This presentation will provide information regarding the decomposition and decontamination of fentanyl using two different oxidative reactions at various temperatures. A step-by-step protocol for the best method of fentanyl decomposition/decontamination and confirmation of the results by Liquid Chromatography/Mass Spectrometry (LC/MS) is provided.

Impact Statement: This research will impact forensic labs and the law enforcement agencies that deal with fentanyl and need to have a reliable protocol for decomposition/decontamination of fentanyl in forensic/law enforcement laboratories. The forensic science and law enforcement communities will significantly benefit from the establishment of this highly reliable fentanyl decontamination protocol.

Abstract Text: Fentanyl is a synthetic opioid that replicates the analgesic and anesthetic effects of naturally occurring opiates. However, it is reported to be 100 times more potent than morphine. Fentanyl was initially classified as a Schedule II drug by the Drug Enforcement Administration (DEA) due to its potential for both physical and psychological abuse; however, it can still be used in medical settings for significant pain relief. However, given the alarming increase in synthetic opioid overdoses over recent years—estimated to reach 700,000 overdose deaths from 2017 through 2024 according to CDC and NIDA—the scheduling of fentanyl was changed to Schedule I by presidential decree this year.

Fentanyl can be deadly in doses of about 2 mg or more, meaning accidental exposure can be fatal. There is a pressing need for a straightforward protocol for the safe decomposition of fentanyl tablets or powder and for the decontamination of surfaces. In this research, we tested several common oxidative agents for the destruction of fentanyl. Two oxidative processes are reported. (1)The combination of hydrogen peroxide and nitric acid under various experimental conditions (temperature and time). While Gas Chromatography/Mass Spectrometry (GC/MS) analysis showed that all organic components were destroyed, nano-Liquid Chromatography/Mass Spectrometry (nLC/MS) indicated that high levels of fentanyl and other organics were still present. (2) We also utilized saturated acidic solutions of Trichloroisocyanuric Acid (TCCA) due to its more aggressive oxidizing capabilities. This method proved successful, as both the GC/MS and nLC/MS instruments failed to detect any remaining organic chemicals after exposure to the saturated TCCA solution. Based on our findings, we developed a protocol for the decomposition of fentanyl, which will be presented. This protocol has also been provided to the DEA for further testing and evaluation at their facility.

This research outlines a systematic approach for fentanyl decomposition and decontamination, accompanied by LC/MS analysis of the degradation products to confirm the destruction of fentanyl to trace levels.

B43 Nitazene Analog Identification Using a Combination of Liquid Chromatography/Mass Spectrometry (LC/MS) and Gas Chromatography/Mass Spectrometry (GC/MS)

Audrey Pless, BS, Sam Houston State University, Huntsville, TX; Oriana C. Ovide, MS, Texas Department of Public Safety, Houston, TX; Kai Allen, BS, Texas Department of Public Safety, Houston, TX*

Learning Objectives: After attending this presentation, attendees will have learned about a proposed analysis scheme to effectively identify nitazene analogs via Liquid Chromatography/Mass Spectrometry (LC/MS) and Gas Chromatography/Mass Spectrometry (GC/MS). The attendees will learn how using the [M+H]+ protonated molecule ion obtained from the LC/MS and retention time information from the GC/MS will be useful in identifying structurally similar nitazene analogs.

Impact Statement: This presentation will impact the forensic science community by providing seized drug chemists with a simple and effective alternative analysis scheme for the identification of nitazenes in casework using LC/MS and GC/MS. This novel identification workflow was tested using already approved equipment and methods within the Texas Department of Public Safety (DPS) laboratory allowing analysts to seamlessly transition this research into casework applications.[1]

Abstract Text: In the past year, the Texas DPS Crime Laboratory has seen an increase in submitted tablet evidence that contains nitazenes, also known as 2-benzylbenzimidazoles. Typically, these compounds are analyzed via GC/MS and identified using the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) for recommended retention time and structural information. However, due to structural similarities and likeness of the nitazenes, these compounds can be difficult to correctly identify.[2] Most of these novel synthetic opioids have nearly identical mass spectra and can have very similar retention times.[3] Crime laboratories may find the need to purchase and analyze several nitazene standards to be confident in the final identification, which can be costly and inefficient. This research proposes an alternative analysis scheme for nitazene analog identification that combines retention time information obtained by GC/MS and the $[M+H]^+$ protonated molecule ion obtained from the LC/MS. The proposed analysis scheme utilizes instrumentation that is already commonly found in crime laboratories and reduces the need to analyze multiple standards when identifying nitazene analogs.

This study examined 15 nitazene analogs: butonitazene, clonitazene, etonitazene, isotonitazene, metonitazene, protodesnitazene, protonitazene, N-desethyl isotonitazene, N-desethyl protonitazene, N-pyrrolidino etodesnitazene, N-pyrrolidino etonitazene, N-pyrrolidino isotonitazene, N-pyrrolidino metonitazene, N-pyrrolidino protodesnitazene, and N-pyrrolidino protonitazene. For LC/MS analysis, the standards were prepared at 1 mg/mL in LC/MS grade methanol, then 300 µL of the solution was combined with 200 µL of methanol in a 500 µL LC/MS reduced vial. Samples were prepared in methanol and placed into inserts for GC/MS analysis. Experimental parameters for both the LC/MS and GC/MS are validated and currently used in casework at the Texas DPS.[1] Retention time studies were also performed on the LC/MS and the GC/MS, consisting of N-pyrrolidino protonitazene, N-pyrrolidino etonitazene, and N-pyrrolidino isotonitazene at low (0.2 mg/mL), mid (0.5 mg/mL), and high (1 mg/mL) concentrations analyzed in quadruplicate.

Results indicated that the proposed analysis scheme utilizing the structural $[M+H]^+$ protonated molecule ion from the LC/MS and retention time information from the GC/MS aided in the identification of nitazenes. LC/MS results determined that the $[M+H]^+$ peak was prominent in the electrospray ionization mass spectrum when analyzed at a cone voltage of 5 eV. Two independent nitazene analogs were analyzed at 0.05 mg/mL to verify the presence of the $[M+H]^+$. This ion was found to be extremely beneficial for the differentiation of nitazene analogs since these compounds have different molecular weights, excluding structural isomers. When the retention time studies were performed on the LC/MS and the GC/MS, the results showed that the retention times on the GC/MS were more consistent and had lower standard deviations when compared to the LC/MS. The proposed analysis scheme was tested on an authentic casework sample that consisted of a tablet containing N-pyrrolidino protonitazene. When prepared with methanol and analyzed on the LC/MS, the $[M+H]^+$ protonated molecule ion was present at 5 eV, which allowed the analyst to select the appropriate standard for the GC/MS retention time comparisons. This study demonstrates a cost effective and easy-to-implement alternative analysis scheme for the identification of nitazenes in forensic casework.

B44 Optimizing a Portable-Capillary Liquid Chromatograph With Diode Array Detection for Illicit Drug Analysis

Lauren Deem, BS, The George Washington University, Washington, DC; Abigail Ladau, BS, The George Washington University, Washington, DC; Ira S. Lurie, PhD, The George Washington University, Washington, DC*

Learning Objectives: After attending this presentation, attendees will understand how 18 illicit drug-related analytes can be detected and separated under a variety of chromatographic conditions using a portable-capillary liquid chromatograph with Diode Array Detection (DAD).

Impact Statement: This presentation will impact the forensic science community by presenting optimized parameters for a capillary-liquid chromatograph with DAD that can be used in the laboratory for the analysis of illicit drugs. This technique is valuable because it offers rapid analysis and low resource requirements while providing two Category B Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) techniques, including liquid chromatography retention time and an Ultraviolet (UV) spectrum for each of the analytes.

Abstract Text: The focus of this project is to determine suitability and optimize the performance of a portable liquid chromatograph with diode array detection for illicit drug analysis. Capillary liquid chromatography with DAD combines high resolution separations with spectral-based compound confirmation in a compact, low-solvent format. Method development involved adjusting mobile phase compositions, including acetonitrile concentration, buffer type, buffer pH, and reverse phase column packings. The systems were evaluated using 18 illicit drug-related analytes from representative drug classes, including stimulants, opioids, opiates, and hallucinogens. Key metrics were assessed for five replicates, including limit of detection, and run-to-run and day-to-day relative retention time repeatability. The range of the LOD was 0.3 – 19.1 ppm, and the average percent relative standard deviation for the run-to-run trials was 1.4%, while the day-to-day average was 5.7%. For these studies, a Waters BEH C18 column and a phosphate buffer/acetonitrile mobile phase were utilized.

The library search function was dependent on identification using relative retention times. Occasionally, especially for day-to-day relative retention time, the software failed to properly identify a drug using a library search of the peak's generated UV spectrum. One way to rectify this would be to either compare samples with standard spectra manually or to implement the ability to search by peak area ratios or peak height ratios of selected DAD wavelengths, which are proportional to the extinction coefficients at those wavelengths. These findings underscore the method's potential for rapid, reliable screening and preliminary identification, particularly in settings where resources and instrument footprint may be limited, while offering further studies to improve the library search implementation.

B45 The Validation of an LC-PDA Method for the Quantitative Analysis of Cannabinoids in Homemade and Commercial Gummies

Ya-Chih (Jessica) Cheng, PhD, The George Washington University, Washington, DC; Walter B. Wilson, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees will gain insight into the challenges and solutions associated with analyzing homemade cannabinoid gummies as well as the accuracy of cannabinoid labeling in commercial gummy products.

Impact Statement: This presentation impacts the forensic community by validating the accuracy of a previously developed gummy extraction method for cannabinoid analysis. By optimizing protocols compatible with Liquid Chromatography-Photodiode Array (LC-PDA), this study helps forensic laboratories adapt to evolving legal requirements and improve their analytical capabilities. It also addresses the unique challenges of analyzing homemade gummies, which vary widely in recipe and composition, and demonstrates the reliability of labeling in commercial cannabinoid gummies.

Abstract Text: The cannabinoid edibles market has grown rapidly after the passage of The Agriculture Improvement Act of 2018 (Farm Bill). Commercial and homemade gummies are now widespread. However, because some cannabinoids remain federally illegal in the United States, it is important to have an effective and validated method to accurately quantify cannabinoids in edible products. The diverse sample matrices in gummy products complicates the extraction of the regulated cannabinoid. Previous research at National Institute of Standard and Technology (NIST) has developed an extraction method compatible with LC-PDA analysis, the method's accuracy requires further evaluation. In this study, homemade gummies were spiked with known concentrations of cannabinoids to assess the accuracy of the extraction method. However, issues such as sample homogeneity and variability in recipes can significantly affect the reliability of analysis. Ingredients like gelatin and pectin, which are commonly used as gummy gelling agents, may also impact the extraction process and quantitation accuracy.

In this study, sampling strategies included analyzing single gummies, pooled samples (n=10), and cryo-ground homogenized gummies were evaluated. The effects of sample volume, freezing, and shaking time on recovery were also investigated. Results showed that sampling strategy did not significantly impact recovery, but larger sample volumes tended to overestimate concentrations. Freezing conditions were further evaluated as part of optimizing the method for highest accuracy. Furthermore, homemade cannabinoid gummies are commonly prepared with gelatin due to its ease of use, whereas most commercial cannabis gummies employ pectin. Therefore, both formulations were evaluated to identify recipe-specific challenges and their impact on method performance. The optimized method was then applied to 15 commercial cannabinoid gummies to evaluate the accuracy of labeled cannabinoid concentrations. While commercial products showed greater uniformity than homemade samples, discrepancies were still observed between labeled and measured values. These findings highlight the importance of method validation when analyzing cannabinoids in complex edible matrices. Careful attention to extraction conditions and sampling strategy is essential, particularly for homemade gummies, and the optimized approach presented here provides practical guidance for forensic laboratories.

B46 Addressing the Oxygen in the Room: A Novel Approach for the Identification of Nitazene Analogs by Oxygenated Species Using DART-MS

Emma Hardwick, BA, Sam Houston State University, Huntsville, TX; Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about a novel way to identify nitazene analogs using Direct Analysis in Real Time-Mass Spectrometry (DART-MS). The audience will learn about how the DART ionization process creates unique oxygenated species that can be used as diagnostic markers for nitazene analogs. This information will provide attendees with a novel approach to identify nitazene analogs when using DART-MS, which provides further support for the utility of DART-MS as a screening technique for nitazene analogs.

Impact Statement: This presentation will impact the forensic science community by providing a novel approach to rapidly identify nitazene analogs using DART-MS. The presence of a unique oxygenated species formed through DART ionization of nitazene analogs provides additional information that will assist forensic scientists with the rapid identification of nitazene analogs.

Abstract Text: Nitazene analogs are Novel Synthetic Opioids (NSOs) that are becoming increasingly prevalent in the United States. Given their increasing prevalence, there is a need for the development of a rapid screening method for nitazene analog identification in forensic laboratories. One rapid screening approach that has gained acceptance for seized drug screening is DART-MS, due to the ability to analyze samples with little to no sample preparation. However, when DART-MS is used to analyze nitazene analogs, oxygenated species are formed. The central hypothesis of this research is that the presence of oxygenated species in DART-MS full scan mass spectra can be used as diagnostic markers for the identification of nitazene analogs.

A DART JumpShot ionization source was coupled with an Agilent Q-TOF mass spectrometer for this study. Both helium and nitrogen source gases were used to analyze 18 nitazene analogs. The oxygenated precursor ion was selected for ss Spectrometry Imaging (MS/MS) analysis, which was collected using a 15-eV collision energy. The standards were prepared at 25 ppm for helium analysis and 100 ppm for nitrogen analysis, to account for poorer ionization efficiency. Samples were pipetted onto the closed end of a glass capillary and, once dry, the glass capillaries were introduced to the source for approximately 10 seconds. All samples were collected in triplicate.

When using helium as the source gas, the full scan mass spectrum for all 18 nitazene analogs contained an ion 14 Da larger than the protonated molecule. Based on accurate mass measurements, this 14 Da difference was attributed to the addition of an oxygen atom and the loss of two hydrogen atoms from the protonated molecule. MS/MS analysis of this oxygenated ion yielded a product ion 14 Da larger than the base peak for the non-oxygenated species. For example, protonitazene typically has a base peak at *m/z* 100.1124 due to its diethyl substitution at the amine moiety. However, when the $[M+H-2H+O]^+$ peak was isolated and fragmented, a prominent peak at *m/z* 114.0914 was observed. This indicates that oxygen addition is occurring at the amine moiety. This same trend was observed for nitazene analogs with different amine moiety substitutions. When nitrogen was used as the source gas, an ion 16 Da larger than the protonated molecule was observed, consistent with an oxygen adduct without the loss of any hydrogen atoms. This $[M+H+O]^+$ ion was observed for all nitazene analogs, although at very low abundance. However, the presence of this ion reveals that the source gas impacts the oxygenated species observed for nitazene analogs analyzed with DART-MS. Furthermore, oxygenated species are not commonly observed when analyzing most controlled substances with DART-MS, and the presence of an oxygenated species in the full scan spectrum is a strong indication that a nitazene analog is present. The identification of these oxygenated species provides diagnostic markers to assist with the identification of nitazene analogs using DART-MS, enabling rapid screening of these potent NSOs.

B47 Distinguishing Positional Isomers of Methylfentanyl

Jennifer Skuches, MS, Drug Enforcement Administration, New York, NY; Brianna C. Singh, BS*, Drug Enforcement Administration, New York, NY*

Learning Objectives: After attending this presentation, attendees will be able to assess and identify the different potential methylfentanyl isomers employing the Drug Enforcement Administration's (DEA's) Global Uniform Analysis and Reporting of Drug-Related Substances (GUARDS) Gas Chromatography/Mass Spectrometry (GC/MS) method.

Impact Statement: This presentation will impact the forensic science community by providing an analytical scheme for use in forensic seized drug analysis to distinguish methylfentanyl isomers utilizing DEA's GC/MS GUARDS method.

Abstract Text: Currently, the United States is experiencing an unprecedented fentanyl epidemic. Through different routes of fentanyl synthesis, modifications can be made to create Fentanyl-Related Compounds (FRCs) that can lead to challenges in their identification. α-Methylfentanyl was first identified in DEA casework in 1981 and closely followed by the identification of 3-methylfentanyl in 1983. Since then, there have been multiple studies conducted to analytically differentiate the various isomers of these FRCs. Over time, the number of structural isomers of methylfentanyl have increased, making the identification more complex.

In the Fall of 2024, DEA Forensic Laboratories started observing indications of methylfentanyl in seized drug samples. In these instances, the methylfentanyl was not confirmed nor was the isomer of the methylfentanyl distinguished due to limits in methodology, reference material availability, and instrumentation. In addition, these samples had other controled substances present such as fentanyl and heroin, as well as non-controled substances such as acetaminophen, caffeine, and xylazine.

Individual analysis was conducted with 15 methylfentanyl isomers using different instrumental techniques, including DEA's GUARDS GC/MS method. Mixes containing the isomers and fentanyl were also tested. Ion fragmentation and retention time differences were key in identification of each of the 15 methylfentanyl isomers. There are a few limitations, but with careful analysis, isomer determination can be achieved. This presentation will provide guidance in analyzing unknown seized drug samples containing methylfentanyl isomers using the DEA-developed GUARDS GC/MS method.

B48 Enhancing Canine Detection Through the International Commission on Detector Dogs (ICODD)

Kenneth G. Furton, PhD, Florida International University, Miami, FL; Kelvin Frank, PhD, Global Forensic and Justice Center and Department of Chemistry and Biochemistry, Florida International University, Miami, FL*

Learning Objectives: After attending this presentation, the attendees will be able to describe the mission, structure, and focus areas of the ICODD.

Impact Statement: The presentation will impact the canine community by demonstrating how global collaboration through ICODD can enhance the overall reliability and efficacy of canine detection disciplines.

Abstract Text: Detector dogs are widely used for the detection of illicit drugs, explosives, live humans, human remains, firearms, ignitable liquid residues, electronics, and other forensic targets due to their highly developed olfactory system. However, despite decades of use across several detection disciplines, there has historically been a lack of global consensus on scientific standards, terminology, and training methodologies. The ICODD, launched by the Global Forensic and Justice Center at Florida International University, was created to address this critical need. ICODD serves as an international body composed of multidisciplinary experts such as canine practitioners, legal experts, and forensic scientists working to improve the performance of detector dog teams through science-based guidelines, standardization, and knowledge-sharing.

This presentation will introduce attendees to the objectives, structure, and ongoing initiatives of ICODD, including efforts to develop international certification protocols and support scientifically validated training methods and standards. The commission also provides a platform for addressing challenges such as variation in national training and certification standards. Case examples will be provided to illustrate how collaborative research and stakeholder engagement are shaping new best practices for canine-assisted detection globally. Online courses developed will be discussed including the ability of participants to achieve a Dogs and Sensors master certificate.

Attendees will gain insight into how global cooperation under ICODD can enhance the reliability, credibility, and effectiveness of canine detection disciplines. This session will benefit the wider forensic and canine community by offering actionable recommendations for implementing internationally recognized best practices and standards in their respective regions.

B49 Illicit Cannabis Cultivation in California: Illegal Pesticides, False Packaging, and Risks to Human Health

Vidia Allison Gokool, PhD, Lawrence Livermore National Laboratory, Livermore, CA*

Learning Objectives: This presentation will share knowledge on an increasingly prevalent threat facing the state of California as well as other states with state-legal medicinal or recreational cannabis cultivation practices. This work characterizes the risks posed by illegal pesticides, current knowledge about illegal use cases, and efforts toward identifying these illegal compounds to advance interdiction efforts.

Impact Statement: This presentation will inform the broader forensic community about a present but underpublicized threat impacting many states across the United States. In addition to threat awareness, this presentation will provide valuable information about the legality of these compounds and how to characterize them using analytical instrumentation, which will aid in local interdiction efforts to remove toxic, illegal pesticides from the public.

Abstract Text: Illegal pesticides have recently been used at licensed and unlicensed cannabis grow sites in California; these chemicals, which are dispersed as chemical fumigants, contain prohibited and uncharacterized chemicals posing risks to nearby humans, soil, ground water, and vegetation. Seizures conducted at illicit marijuana grow sites throughout the state of California have revealed a pervasive use of illegal pesticides with a common reoccurrence of "Blue Bag Pesticides." These pesticides violate multiple laws and statues regarding their labeling, chemical contents, and directions for use. This work discusses the current landscape of illegal pesticides in cannabis cultivation and the larger risks they pose to humans and the environment.

The contents of unused "Blue Bag Pesticides" have been analyzed by Gas Chromatography/Mass Spectrometry (GC/MS), Pyrolysis-GC/MS (Py-GC/MS), two-dimensional Gas Chromatography/Time Of Flight/Mass Spectrometry (GCxGC/TOF/MS), and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) to characterize their chemical compositions. Multiple techniques were undertaken due to the unique physical characteristics of the samples. The complementary use of GC/MS and LC/MS approaches creates an overlapping range of detection from volatile to non-volatile compounds with GCxGC allowing for further deconvolution of chromatographic peaks. Additionally, the high-resolution GC/MS and LC/MS techniques increase confidence in database comparison and theoretical structural elucidation, allowing for a more comprehensive characterization of the previously unknown seized fumigant materials. This chemical fingerprinting serves as the first step toward mitigating public exposure to these chemicals through cannabis materials and off-target exposures. Further investigation of their environmental effects may reveal additional forensic indicators of illegal cultivation activities, thereby creating additional safeguards for the general public.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. This work was supported by LDRD project tracking code 25-ERD-025, tracking number LLNL-ABS-2003021.

B50 Quantifying Dosage Risk: Fentanyl Concentrations in Counterfeit Drugs From Border Seizures

Mia Borrelli, MSFS, Center for Forensic Science and Research & Education, Horsham, PA; Amanda L. A Mohr, MS, The Center for Forensic Science Research and Education, Horsham, PA; Barry K. Logan, PhD, Center for Forensic Science Research & Education, Horsham, PA; Thom Browne, Jr., MA, Colombo Plan, Huachuca City, AZ*

Learning Objectives: After attending this presentation, attendees will be able to discuss the significance of differences and changes in the potency of fentanyl in seized drug exhibits in the illicit drug supply across multiple seizures and border crossings. Attendees will also be able to identify the other substances most frequently found in counterfeit fentanyl tablets.

Impact Statement: Understanding patterns of fentanyl concentrations in counterfeit pills seized at the United States Southwest border provides critical benefits to the forensic science community by helping laboratories anticipate potency variability, understanding patterns of overdose outbreaks and manner of death in fatalities, and providing public health information to better educate people who use drugs about threats in the drug supply. This data guides resource allocation for analytical testing, enhances accuracy in cause-of-death determinations, and supports research on evolving drug supply threats, strengthening forensic and public safety responses.

Abstract Text: Illicitly manufactured fentanyl dominates the United States drug supply, frequently being found in combination with other drugs, and pressed into counterfeit tablets. These tablets are typically manufactured in uncontrolled environments, leading to highly variable, often lethal, fentanyl doses. The Drug Enforcement Administration (DEA) has identified 2mg of fentanyl as a potentially lethal dose; however, considerations like tolerance, co-ingestion, opioid naivety, route of administration, and body weight, lesser amounts can also be lethal.

Counterfeit pills (n=150) were collected from January to March 2025 at various locations on the United States Southwest border. Due to confidentiality, the different ports from where the samples were seized are numbered 1-4 in Table 1. All samples were blue “M 30” tablets. Sixty-five of the tablets underwent a comprehensive characterization workflow that included color (RGB) measurement, dimensions, monograph description, qualitative analysis of main ingredient, adulterants, precursors and reaction by-products, by Gas Chromatograph/Mass Spectrometry (GC/MS) and Liquid Chromatography/Quadrupole Time-Of-Flight (LC/QTOF), and quantitation of popular seized drugs and some adulterants by Liquid Chromatography/Tandem Mass Spectrometry (LC/MSMS).

Fentanyl and acetaminophen were identified in all tablets tested (n=65). The mean (±SD) amount of fentanyl per tablet across all 65 exhibits tested ranged from 0.7 to 2.6 mg, median amount of fentanyl per tablet across all 65 exhibits tested ranged from 0.7 to 2.8 mg, and range of fentanyl across all 65 tablets tested was 0.7 to 3.5 mg, with the individual variability within cases shown in Table 1.

Table 1. Fentanyl concentrations in cases seized in 2025 to date.

	N	Port of Seizure	Date of Seizure	Mean mg of Fentanyl per Tablet	Range mg of Fentanyl per Tablet	Median mg of Fentanyl per Tablet	Other Compounds Identified (Relative Parts Calculation, Main Component = 1p)
Case 1	7	Port 1	January 2025	2.0(±0.1)	1.9-2.1	2.0	Acetaminophen(3.7p) Metamizole(0.6p) t-Boc Norfentanyl(trace) 4-ANPP(0.1p) Ethyl 4-ANPP(trace) Despropionyl para-Methylfentanyl(trace) Acetyl Fentanyl(trace) Fentanyl(1p) Phenethyl 4-ANPP(trace)
Case 2	21	Port 2	January 2025	1.9(±0.6)	1.2-2.9	1.9	Acetaminophen(82.6p) N-Phenyl propanamide(0.4p) Lidocaine(17.4p) Metamizole(20.4p) 4-ANPP(0.3p) Fentanyl(1p) BTMPS(3.9p)
Case 3	20	Port 3	February 2025	2.6(±0.4)	2.0-3.5	2.8	Acetaminophen(27.8p) N-Phenyl propanamide(0.2p) Lidocaine(6.5p) Metamizole(8.2p) 4-ANPP(trace) Ethyl 4-ANPP(trace) Fentanyl(1p) BTMPS(2.6p)

Copyright 2026 by the AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained by the AAFS.

Case 4	10	Port 1	March 2025	1.4(±0.1)	1.3-1.5	1.4	Acetaminophen(4.6p) 4-Anilinopiperidine(0.1p) Metamizole(2.0p) 4-ANPP(0.1p) Ethyl 4-ANPP(trace) Despropionyl para-Methylfentanyl(trace) Acetyl Fentanyl(trace) Fentanyl(1p) BTMPS(trace) Phenethyl 4-ANPP(trace)
Case 5	7	Port 4	March 2025	0.7(±0.03)	0.7-0.8	0.7	Acetaminophen(262.2p) N-Phenyl propanamide(0.2p) Lidocaine(27.1p) Xylazine(0.7p) Metamizole(95.2p) 4-ANPP(0.1p) Fentanyl(1p) BTMPS(2.9p)

The tablets in this case series were all manufactured to resemble pharmaceutical 30 mg oxycodone tablets. The data shows the significant variability of the fentanyl dose from case to case, port to port, and even within each case. Data from 2023 and 2024 showed mean (±SD) of fentanyl as follows: 2023: 2.1 (±1.0) mg, 2024: 1.7 (±0.9) mg. This compares to the mean (±SD) of 2025 so far at 1.9 (±0.7) mg. The mean for 2025 only encompasses the samples tested for 2025 so far, so that value could vary.

The unpredictable dosing not only endangers users, but also complicates forensic interpretation and investigations, emphasizing the need for rigorous quantitative monitoring and surveillance, to improve public awareness of the dangers posed by counterfeit fentanyl-laced pills.

B51 An Evaluation of Deactivations on Gas Chromatographic Stationary Phases for the Analysis of Seized Drugs of Abuse

Amanda Ridgon, BS, Restek Corporation, Bellafonte, PA; Corby Hilliard, Restek Corporation, Bellefonte, PA; Jared Burkhart, BSc, Restek Corporation, Bellefonte, PA; Jamie York, PhD, Restek Corporation, Bellefonte, PA*

Learning Objectives: This presentation will help attendees understand the challenges with the analysis of a large suite of seized drugs of abuse using a variety of deactivations on a 5% diphenyl-polysiloxane stationary phases. They will be introduced to a method that reliably identifies many different classes of compounds, including ones with basic, acidic, and neutral moieties.

Impact Statement: There is currently not sufficient information on column performance for a comprehensive list of drugs of abuse analyzed using gas chromatography. This presentation will demonstrate percent Relative Standard Deviations (%RSDs) for different deactivations and help the user in choosing a column that best fits their specific targeted compounds.

Abstract Text: Gas Chromatography/Mass Spectrometry (GC/MS) is often used for screening seized drugs due to its ease of use and specificity. This technique is particularly advantageous because it can be performed without the need for chemical derivatization, a process that is often time-consuming and complex. However, when drugs of abuse are analyzed in their underivatized form, their active functional groups can interact with the active sites on the surface of the fused silica column. This interaction can result in poor peak shape and reduced recoveries, potentially leading to inaccurate or unreliable results.

Recent advancements in column chemistry, particularly the development of deactivations that minimize the presence of active silanols on the fused silica surface, have significantly improved the ability to analyze active compounds without derivatization. Given the highly reactive nature of the compounds involved, column deactivation plays a crucial role in achieving reliable results.

In this study, we evaluated the impact of column deactivation on a 5% diphenyl-polysiloxane stationary phase (5-type) to identify the optimal deactivation for analyzing a broad range of underivatized drugs that includes compounds that contain acidic, basic, and neutral moieties. As the complexity of drugs of abuse continues to increase, laboratories are challenged to implement more comprehensive lists of compounds in their methods, ensuring they can detect a wider range of substances, including New Psychoactive Compounds (NPS).

B52 What's in the Powder? Evaluating Fentanyl Test Strip Sensitivity to Common Household Items in Chemical Emergency Response Scenarios

Kate Mongold, MS, University of Wisconsin-Madison, Madison, WI; Heather Barkholtz, PhD, University of Wisconsin-Madison, Madison, WI; Meshel Lange, MS, Wisconsin State Laboratory of Hygiene, Madison, WI; Mason Shields, BS, Wisconsin State Laboratory of Hygiene, Madison, WI*

Learning Objectives: This presentation will: describe the analytical performance (including Limit Of Detection [LOD] and potential interferences) of BTNX Fentanyl Test Strips (FTS) when used in the presence of common diluents, interpret and evaluate FTS results near LOD in realistic emergency response scenarios , and identify and discuss the limitations of the immunoassay-based drug detection tools in field settings

Impact Statement: Many researchers have tested the effects of fentanyl analogs and psychoactive adulterants on BTNX FTS, but there is no published research on whether FTS are affected by the presence of common household diluents. FTS are an impactful harm reduction and emergency response tool and understanding how FTS interact with diluents will support their use as a quick and cost-effective screening method in scenarios involving unknown substances. This work expands FTS application to include assessment of chemical threats by first responders and Hazardous Material (HazMat) teams operating outside of laboratory environments.

Abstract Text: The increasing prevalence of opioid misuse, particularly the adulteration of illicit substances with fentanyl, has heightened the need for effective field detection methods for unknown powders. First responders, including chemical emergency response and HazMat teams, face significant challenges in assessing chemical threats in real-time without the resources of a controlled laboratory environment. Immunoassay test strips, such as those produced by BTNX Inc., are commonly used for drug detection and are considered potential tools for identifying fentanyl in emergency scenarios. However, the impact of common diluents (substances such as sugar, flour, and other commonplace additives) on the accuracy of these test strips is unexplored.

This study evaluates the LOD of BTNX FTS in the presence of various diluents commonly found in emergency situations. The experimental LOD was determined to be 0.05 µg/mL, significantly lower than the manufacturer's advertised LOD of 0.20 µg/mL. While no false positives were observed with diluents alone, the presence of diluents in fentanyl solutions altered the test strip results, requiring higher concentrations of fentanyl to achieve a positive reading. Results were often difficult to interpret, particularly near the LOD, which could pose challenges for first responders in real-world scenarios. This work is the first to assess the application of test strips for chemical emergency response assessment of unknown powders and highlights the potential for these strips to be utilized in emergency response settings, provided that appropriate training and awareness of limitations are established.

B53 The Impact of Environmental Contaminants on the Accuracy of Bacterial-Signature-Based Identification of Human Saliva Samples

Briley Peacher, BS, Virginia Commonwealth University, Richmond, VA; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: One learning objective is to assess the effect of contaminants on the bacterial composition of saliva samples. Another learning objective is understanding the conclusions on contaminants' impact on DNA yield.

Impact Statement: The presentation will impact the forensic science community by allowing insight into how various environmental contaminants impact saliva identification using a bacterial signature-based method. Changing the bacterial composition of the evidence sample may impact the accuracy of the bacterial signature-based method, which would be beneficial to understand and work with in the forensic science community.

Abstract Text: Saliva is a valuable source of DNA in forensic investigations and can be found on various surfaces at crime scenes. Saliva can be present in spit, tissues, drinking glasses, cigarettes, envelope flaps, and even bite marks from victims or suspects. Evidence samples are often mixed with various contaminants from the scene, such as dirt and cleaning agents, which can cause Polymerase Chain Reaction (PCR) inhibition or can change the microbial profile of the concerned sample. Changing the bacterial composition of the evidence sample may impact the accuracy of the bacterial signature-based method. However, little research has examined the effects of environmental contaminants on DNA recovery from saliva.

This study evaluates the impact of bleach, Lysol, laundry detergent, and soil on bacterial composition and DNA yield from saliva samples. Forty saliva samples were collected from eight volunteers and mixed with contaminants. DNA extraction was done using the QIAgen DNA Investigator kit. Variable region 4 (V4) of 16S rDNA was amplified from extracted DNA, and the amplified product was cleaned and sequenced on the MiSeq FGx platform using the dual-index strategy. Bacterial community structure differs significantly in saliva mixed with soil samples compared to the other mixed and pure saliva samples. Except in some soil samples, indicator bacteria associated with human saliva (e.g., *Streptococcus*, *Veillonella*, and *Haemophilus*) were present in all samples included in this study. This study shows that the saliva mixed with soil may impact the prediction accuracy of the bacterial signature-based method for body fluid identification. The prediction accuracy of saliva mixed with Lysol and detergent may not be significantly impacted.

B54 Investigating New Barcode Markers to Distinguish Kratom Varieties

Jasmine L. Sierra, BS, Sam Houston State University, San Marcos, TX; Cesar E. Cantu Jr., Jr., PhD, St. Mary's University, San Antonio, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Kari Graham, PhD, Center for Human Identification, Venus, TX*

Learning Objectives: After attending this presentation, attendees will understand the utility of novel chloroplast barcode regions and kratom-specific primer sets for differentiating among products belonging to *Mitragyna speciosa*.

Impact Statement: This presentation will impact the forensic science community by advancing the development of a DNA-based identification and sourcing tool for *Mitragyna speciosa*. By introducing new barcode regions and evaluating an expanded range of commercial products, including traditional kratom tea powders and non-traditional products such as gummies, this research addresses the limitations of universal plant barcodes and contributes to more accurate identification and potential source attribution of kratom in forensic casework, especially in jurisdictions where it is regulated or prohibited.

Abstract Text: Kratom (*Mitragyna speciosa*) is a psychoactive plant increasingly found in forensic casework due to its association with polydrug use, fatalities, and its complex legal status across U.S. jurisdictions. Reliable species identification and source attribution of kratom products are critical, but existing forensic approaches are limited by variability in alkaloid content and the lack of comprehensive DNA sequence data, even though the genetic signature of the plant remains consistent. Unlike animals, for which the COI barcode is broadly effective, no single plant barcode provides sufficient resolution across taxa. Previous research assessed universal barcode markers (ITS, matK, rbcL, trnH-psbA) and found limited intraspecific variation in M. speciosa, suggesting that additional, more targeted barcodes may improve forensic utility.[1]

In this study, we selected four novel primer sets for chloroplast intergenic barcode regions (trnL-trnF, rpl14-16, petA-psbJ, and ndhF-rpl32) and designed kratom specific primer sets in-silico. These targets were chosen based on conservation flanking variable intergenic spacers and alignment with the limited M. speciosa sequences currently available in GenBank. Annealing temperatures were optimized for successful Sanger sequencing, and performance was assessed across 28 powdered kratom tea products. Because available sequence data for related Mitragyna species are sparse, inter-species variation remains unknown; however, all novel sequences generated in this study will be submitted to GenBank to help address this gap.

This research not only evaluates promising markers for kratom-specific barcoding but also emphasizes the need for expanding plant forensic reference databases. Improved marker resolution and expanded sequencing data are essential steps toward developing robust forensic tools for identification and source tracking of kratom in regulatory and legal contexts.

B55 An Evaluation of OpiumPlex for Genetic Profiling of the Opium Poppy

Greta Hundtofte, BS, Sam Houston State University, Huntsville, TX; Sara Willer, MS, DNA Labs International, Deerfield Beach, FL; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will learn how one multiplex from the previously published OpiumPlex Short Tandem Repeat (STR) panel was evaluated and optimized for the identification and differentiation of *Papaver somniferum* L. (opium poppy) variants, with relevance to forensic investigations involving plant-derived opioids.

Impact Statement: This presentation provides the forensic science community with an optimized and independently evaluated genetic assay for identifying *P. somniferum*. These findings support the development of complementary genetic tools that may assist in sourcing materials associated with illicit opioid production, particularly opioids originating from the opium poppy plant, including heroin.

Abstract Text: The opium poppy produces alkaloids that serve as the foundation for many opioid drugs, including morphine and heroin. While synthetic opioids such as fentanyl have dominated the illicit drug landscape in recent years, efforts to control their production and distribution, including restrictions on precursor chemicals, have contributed to a resurgence in heroin manufacturing. As a result, plant-derived opioids remain a persistent and evolving concern, reinforcing the need for tools that can trace these substances back to their biological origin.

Traditional forensic approaches rely on analytical chemistry to identify opioid compounds. However, advances in forensic genetics, such as the publication of the
P. somniferum genome and successful DNA extraction from processed materials like opium and heroin, offer a complementary path for identifying and sourcing these substances. In 2021, Vašek et al. introduced OpiumPlex, an STR assay targeting 27 loci that successfully distinguished 30 out of 36 tested *P. somniferum* variants, highlighting its potential to support origin attribution of opium poppy materials used in illicit drug production.[1]

The present study provides the first independent evaluation and optimization of one of the three OpiumPlex multiplexes, including development of an allelic ladder. Although the original assay showed promising discriminatory power, the published protocol could not be reliably replicated under standard forensic laboratory conditions. In this study, key parameters such as primer concentrations and Polymerase Chain Reaction (PCR) cycling conditions were reoptimized to improve amplification performance, reproducibility, and sensitivity. The refined assay was used to genotype 20 opium poppy seed samples, revealing six distinct genotypes with low allelic variation. The assay showed no cross reactivity with non-target species and successfully amplified as little as 0.5 nanograms of input DNA.

These findings illustrate the potential for STR-based genotyping to complement chemical profiling by enabling source attribution of opium poppy-derived materials. As heroin production increases in response to evolving drug control efforts, genetic tools such as this assay can help forensic laboratories meet emerging investigative needs. Future work will focus on developing enhanced multiplexes by incorporating additional and more discriminatory STR markers, such as those published by Kaňuková et al. to improve resolution and broaden forensic applicability.[2]

B56 Analyzing the Effects of Time and Temperature on SNP Markers in Fingernails to Indicate Asian and African American Descent

Heather G. Coyle, PhD, University of New Haven, West Haven, CT; Kelly G. Murphy, BS, University of New Haven, West Haven, CT*

Learning Objectives: This study analyzes the effect of time and temperature on the viability of Single Nucleotide Polymorphisms (SNP) markers in fingernails. This includes preliminary population data for markers rs12913832 on the HERC2 gene, rs1800407 on the OCA2 gene, and rs26722 on the SLC45A2 gene from three populations: African American, Asian, and Caucasian. Topics including best storage practices for fingernails, optimized DNA extraction protocols, and current progress will be discussed. Attendees will learn about the practical application of SNP markers for mass disaster victim identification and how fingernails can serve as a noninvasive evidentiary aid in unidentified human remains cases.

Impact Statement: SNP markers have been used in forensic science to provide investigative leads, which can indicate physical traits of an individual, medical conditions, predispositions to diseases, and more. While SNP markers can be extremely useful in the forensic field, not enough research has been completed to determine their parameters, how reliable they are, and factors that can affect their viability. This research study analyzes the effect of time and temperature on extracted DNA from fingernails for the purpose of SNP marker testing, external variables which adversely affect SNP analysis success.

Abstract Text: SNPs are used in forensic science to provide investigative leads, but limited research has been done to determine the reliability of these markers when exposed to external factors. Used to identify unidentified human remains from 9/11, SNP markers can indicate phenotypic traits, predisposition to diseases, how an individual's body may react towards medication, etc.[1-4] SNP markers can be used to determine the specific region an individual's ancestry originates from.[5] Many of the ways SNP markers are extracted from unidentified human remains are quite invasive, commonly being extracted from bones or teeth.[1,6] Preliminary studies have shown that, while in low concentrations, DNA can be extracted from fingernails for SNP analysis.[7-10] This study uses a small sample group to record which SNPs are commonly seen in populations and tests the resilience of SNP markers extracted from fingernails when exposed to varying temperatures for specified durations of time. Previous studies have found that DNA can be extracted from fingernails and analyzed for over 20 years when stored at room temperature (25ºC) or refrigerated (4ºC).[11] It is hypothesized that fingernails stored at 56 ºC may require optimization of extraction protocols and many Polymerase Chain Reaction (PCR) cycles to generate an accurate result comparative to when stored at room temperature. As fingernails degrade over time, the longer samples are stored will also impact the DNA extraction process and SNP analysis.

Fingernail samples were exposed to temperatures 25ºC or 56ºC for either 1 week, 2 weeks, 1 month, or 2 months, examining three SNP markers: rs12913832 on the HERC2 gene, rs1800407 on the OCA2 gene, and rs26722 on the SLC45A2 gene from three populations: African American, Asian, and Caucasian. Sixty participants, 20 from each population, were asked to provide a buccal swab and select individuals, approximately five from each population, provided five fingernail samples in two-week increments. DNA was extracted from the buccal swabs using Invitrogen's PureLink Genomic DNA Kit, the NanoDrop One Microvolume UV-VIS Spectrophotometer and Applied Biosystems's Quantifiler HP and Trio DNA Quantification Kit were used for DNA quantification, and SNPs were analyzed using a custom SNP TaqMan Assay protocol adapted by Emily Seigel. Fingernails went through a cleaning procedure, BioClone's One-Step Touch DNA Purification Kit was used for DNA extraction, and quantification and SNP marker analysis followed the same protocols as the buccal swabs.[12]

Twenty-three buccal swabs and 122 fingernail samples have been collected. The weights of the fingernail samples have been logged and averaged within populations, approximately 0.028g overall per sample. DNA quantitation values of extracted fingernails averaged 557.125ng/uL with moderate contaminants when nails were untreated and stored for one month. Research for SNP profiling is in progress and is anticipated to be available by February 2026. Current results indicate that SNP analysis will be successful at all time points prior to one month when stored at room temperature, although the success rate at 56ºC is unknown at this time.

B57 Sub-Regional Biogeographic Inference for East Asian Populations Using 165 AISNPs and Machine Learning

Sohee Cho, PhD, Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Sojung Lim, MD, Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Soong Deok Lee, MD, PhD, Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Learning Objectives: After attending this presentation, the attendees will gain insight into the potential of differentiating sub-regional East Asian populations using 165 Ancestry Informative Single Nucleotide Polymorphisms (AISNPs) with machine learning approaches. They will also gain a better understanding of the genetic substructure across Asian populations, which can contribute to improved resolution in biogeographic origin classification.

Impact Statement: This presentation will impact the forensic science community by providing insights into the genetic characteristics of a large number of individuals from Northeast, Southeast, and South Asia investigated using 165 AISNPs, thereby contributing to the development of scientific infrastructure that supports biogeographic ancestry inference, particularly in cases involving individuals of Asian origin.

Abstract Text: Inferring an individual's geographic origin from biological evidence can provide valuable investigative leads in the absence of a DNA database match. However, most current ancestry inference tools primarily classify ancestry at the continental level and often group East Asian populations into a single cluster. This broad categorization limits the resolution of the biogeographic origin predictions for individuals from East Asia. This study aimed to address the limitations of existing ancestry inference tools by compiling a more representative dataset of Asian populations and developing a prediction model to classify individuals into Northeast Asian (NEA), Southeast Asian (SEA), and South Asian (SA) groups. Using 165 autosomal SNPs included in the commercial Precision ID Ancestry Panel, we examined the genetic diversity, developed classification models using machine learning algorithms, and evaluated their performance.

The results revealed similar patterns of genetic diversity between the NEA and SEA groups, whereas the SA group displayed a distinct genetic profile. Pairwise Forensic Statistical Tool (FST) analysis indicated the closest genetic distance between the NEA and SEA groups and the greatest distance between the NEA and SA groups. This pattern of differentiation was further supported by the STRUCTURE analysis, which showed a clear separation of the SA group from the NEA and SEA groups. Geographic origin classification models were constructed using six machine learning algorithms: logistic regression, naïve Bayes, One-vs-Rest (OvR) Support Vector Machine (SVM), One-vs-One (OvO) SVM, random forest, and LightGBM. Among these, the random forest and LightGBM models achieved the highest overall accuracy, followed by naïve Bayes, logistic regression, OvR SVM, and OvO SVM. The random forest model yielded F1-scores of 77.57% for NEA, 92.21% for SEA, and 98.92% for SA. The LightGBM model demonstrated a more balanced performance, with F1-score of 82.24% for NEA, 85.71% for SEA, and 98.82% for SA. These consistent patterns across analyses suggest that the SA group exhibits distinct genetic diversity compared to the NEA and SEA groups.

In contrast, the genetic differentiation between northern and southern East Asian groups appeared less distinct than the differentiation along the east-west axis. This may be attributed to the complex demographic history and genetic admixture between northern and southern Chinese populations. Notably, a random forest model excluding Chinese samples yielded improved classification performance and suggested that several Chinese populations exhibit mixed ancestry patterns between NEA and SEA depending on their geographic location. These findings highlight the importance of incorporating comprehensive and balanced datasets to develop more refined and reliable ancestry inference models at the sub-regional level.

B58 The Genetic Evidence Trail: Investigating MicroRNA Markers and Their Connection to Body Mass Index

Daja R. Bonilla, BSFS, Virginia Commonwealth University Forensic Science Department, Richmond, VA; J. Paul Brooks, PhD, Virginia Commonwealth University, Richmond, VA; Sarah Seashols-Williams, PhD, Virginia Commonwealth University Department of Forensic Science, Richmond, VA; Tracey Dawson Green, PhD, Dept of Forensic Science, Virginia Commonwealth University, Richmond, VA; Xiaomeng (Simone) Yang, MS, Integrative Life Sciences PhD Program, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: This presentation introduces an innovative forensic DNA phenotyping method leveraging metabolism-associated microRNA markers to predict an individual's body weight category using DNA extracted from dried whole blood samples. Attendees will also explore how incorporating this additional physical characteristic can support investigations involving unidentified individuals.

Impact Statement: This research could provide the advantage of narrowing the pool of possible suspects or missing persons to consider as subjects of interest by introducing useful microRNA markers for accurately predicting the body weight class of unknown individuals.

Abstract Text: Current forensic laboratory practice for profiling suspects relies on traditional Short Tandem Repeat (STR) testing to generate a DNA profile of the individual. Forensic DNA Phenotyping (FDP) is a method that aids in predicting a person's Externally Visible Characteristics (EVCs), offering investigators more detail when in pursuit of an unidentified suspect.[1] This approach is varied, with identified biomarkers within DNA methylation sites, variation at Single Nucleotide Polymorphisms (SNPs), and, recently, microRNA (miRNA) expression.[2] Notably, SNP markers have yielded robust predictions in static, or unchanging EVCs, such as eye and hair color, using high-performance systems such as IrisPlex and HIrisPlex and are in current use in High-Throughput Sequencing (HTS) panels commercially available for forensic casework.[3,4] Research in DNA methylation has demonstrated successful age prediction results within a ±5-year error range. However, important phenotypic traits such as Body Mass Index (BMI) and weight classes have yet to be explored.

miRNAs are ~22 nt long, non-coding, single-stranded RNAs that post-transcriptionally mediate gene expression.[5] These small molecules are often encapsulated in exosomes that provide them with exceptional stability and make them ideal for forensic samples subjected to long-term storage or environmental degradation.[6] Biomedical research has found miRNAs to be responsible for regulating BMI-associated genes such as adipogenesis, cholesterol, and fatty acid metabolism, which in turn affect weight and fat percentage.

This project investigates a novel FDP approach by exploiting miRNA expression in DNA extracts from blood samples of 100 donors of various ages, heights, weights, and ethnicities to accurately predict body weight composition. Detecting miRNAs from DNA extracts reduces sample use and processing time and provides the foundation for seamless adoption into existing workflows and faster delivery of valuable identity information.

Marker discovery was accomplished by collecting blood samples under approved human subjects protocols, performing Bioelectrical Impedance Analysis (BIA) for body composition measurement, and identifying candidate miRNAs via HTS. Once identified, potential candidates were analyzed using Real-Time quantitative Polymerase Chain Reaction (RTqPCR) in DNase-treated DNA extracts. While potential markers miR-122-5p and miR-1299 were unsuccessful due to no observed correlation in expression against body composition groups, miR-486-3p demonstrated a positive correlation to BMI, explaining approximately 7% of the variation observed as BMI increased when normalized using miR-16-5p as a reference miRNA.

In summary, miR-486-3p has demonstrated a close association between BMI/body weight and miRNA expression in blood DNA extracts, and miR-16-5p was found to express little variation from sample to sample, supporting its use as a reference gene. Future work will include integration of the identified miRNAs into a prediction model.

B59 That's Some Pig: Protocol Optimization for the Analysis of DNA in Unpulverized Cremated Remains

Kendall Kroha, MS, Charles R Step Funeral Home, Rochester Hills, MI; Stephanie Gladyck, PhD, Madonna University, Livonia, MI; Austin Wickham, MS, SeqOnce Biosciences Inc., Freeport, MI*

Learning Objectives: Attendees will learn a validated method for extracting mitochondrial DNA from unpulverized cremated remains, using a protocol refined through porcine proxies and successfully applied to human samples.

Impact Statement: This presentation will enhance the forensic science community by providing a reliable DNA extraction method for identifying cremated remains adaptable to real-world cases. It can improve performance in criminal investigations, mass disaster victim identification, and military causalities.

Abstract Text: The identification of cremated remains has long been a challenge for law enforcement and the broader field of forensic science. Having a method for extracting a genetic profile from cremains would provide valuable information for criminal investigations and disaster response, including the positive identification of cremated decedents or in situations where cremains have been comingled or switched. This research can be extrapolated to assist in homicide investigation of burnt remains, military personnel deaths in action, and mass disasters.

This study was split into two phases. Phase one assessed the efficacy of using unpulverized cremated *Sus scrofa domesticus* remains as a proxy for human cremains to optimize a protocol for the extraction of mitochondrial DNA (mtDNA). Porcine bone is frequently used as a proxy due to its similarities in size, structure, and genetic makeup to that of humans.[1-8] The cranium of a pig was selected for cremation due to the volume of bone and privately cremated at a temperature of 1,600°C for 105 minutes. Samples were chosen for extraction based on the amount of compact bone retained in the fragment. Phase two applied the optimized protocol to human unpulverized cremated remains. A modified lysis protocol was used in conjunction with an established extraction protocol. Extracted DNA was amplified by traditional Polymerase Chain Reaction (PCR) and analyzed through capillary electrophoresis.

Results demonstrated that a mtDNA genetic profile can be isolated and successfully analyzed from unpulverized cremated remains for identification. When applied to the human cremains in the study, preliminary results showed the mitochondrial haplotype was consistent with the maternal cousin's sample. Additionally, another haplotype was present in the unpulverized cremains, which occurred often during the period the cremation took place.[9] Future research will use the established protocol to determine how many individuals are present in the cremains.

B60 Studying Human Decomposition Under Dry, Hot Desert Conditions: An Environmental Simulation Experiment

Ashley Kaufman, BS, Sam Houston State University, Huntsville, TX; Sheree R. Hughes, PhD, Sam Houston State University, Huntsville, TX; Mayra Eduardoff, PhD, Sam Houston State University, Conroe, TX*

Learning Objectives: Attendees will gain insight into how extreme environmental factors, specifically desert-like Ultraviolet (UV) radiation and heat, affect the decomposition of human remains and the preservation of DNA in various tissue types. We will present findings from a controlled study simulating conditions of the Chihuahuan Desert, with a focus on temporal DNA degradation in skin, muscle, nail, and bone samples. Participants will learn how these environmental stressors impact tissue viability for DNA recovery and the implications for forensic identification in arid climates.

Impact Statement: Each year, hundreds of unidentified human remains are recovered in the desert regions along the United States-Mexico border, where exposure to extreme environmental stressors such as heat and UV radiation complicates recovery and identification efforts.[1,2] There is currently no operational human decomposition facility located in such a climate, making it impossible to directly study DNA degradation in desert conditions. This research establishes a proof-of-concept for environmental simulations to address this gap and generate insights critical for both forensic casework and humanitarian responses involving the recovery and identification of human remains.

Abstract Text: Unidentified human remains are frequently discovered in arid regions of the southern United States, particularly along the United States-Mexico border where migrants often perish in extreme conditions.[1-3]

The Chihuahuan Desert, spanning southern New Mexico, West Texas, and northern Mexico, presents intense environmental challenges, including high UV radiation, extreme heat, and low humidity. These factors promote either rapid mummification or accelerated decomposition, both of which complicate biological recovery and DNA analysis.[4-6]

To date, there is no human taphonomic facility operating in a desert climate, limiting the ability to study DNA preservation from decomposing human cadavers in such settings. To address this, we conducted a controlled simulation using three right forearms from different body donors at the Southeast Texas Applied Forensic Science (STAFS) facility at Sam Houston State University in Huntsville, TX. The forearms were placed in a 60-gallon terrarium containing a desert-like substrate of sand, gravel, and soil. The setup recreated 4 months of peak summer conditions of the Chihuahuan Desert, including daytime temperatures of 38°C and nighttime lows of 22°C, relative humidity between 15% and 20%, and 14 hours of daily UVB exposure (10.0 desert strength rating).[7] Environmental variables were controlled using a digital hygrometer and thermometer, programmable thermostat and timer, ceramic heating elements, and ventilation fans.

Tissue samples (including skin, skin swabs, muscle, biopsy punch, nails, and bone (radius/ulna) were collected at timepoint 0 (placement) and then monthly for four months. Photographic documentation occurred biweekly, and temperature and humidity were recorded five times per week. Control samples were collected in parallel from replicate limbs placed on the ground surface under natural conditions at STAFS. DNA was extracted using either a semi-automated or manual methods, quantified, and subjected to Short Tandem Repeat (STR) typing using standard forensic protocols. Overall, results demonstrated clear progression of mummification in the desert-exposed remains, accompanied by a marked decrease in DNA recovery over time and in relation to surface decomposing remains at STAFS.

This environmental simulation offers a new approach toward understanding the effects of continuous dry heat and UV radiation on DNA preservation and ability to generate STR profiles. It also provides a scalable approach for future research and forensic preparedness in arid border regions, with direct applications to real-world humanitarian identification efforts.

B61 The Umbilical Cord as a Novel DNA Sample for Comparison to Unidentified Human Remains

Adelee J. Conner, MFS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA; Cory D. Lawton, MFS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA; David A. Orbin, MFS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA; Ashley N. Platt, MS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA; Stephanie H. Storino, MPS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA*

Learning Objectives: After attending this presentation, attendees will understand the potential value of the umbilical cord as an assumed reference sample. Additionally, they will have further information on overcoming the unique challenges presented by this type of sample and the quality of the data that could be generated from an umbilical cord sample using common DNA methods.

Impact Statement: This presentation will impact the forensic science community by aiding in expanding the scope of the search for assumed reference samples. This may allow for direct comparisons to Unidentified Human Remains (UHR) where previously no sample was available.

Abstract Text: When UHR are recovered, it can be difficult to obtain suitable reference samples for comparison. Often, individuals have been missing for several years or have led a transient lifestyle, which complicates the procurement of reference samples. Without an assumed reference, a case may require additional processing such as kinship analysis, which can be both cost and time intensive. This highlights the importance of obtaining assumed reference samples and the need to seek out other opportunities to find samples suitable for comparison.

The Allegheny County Office of the Medical Examiner had the opportunity to develop an assumed reference profile from an umbilical cord in order to perform a direct comparison to skeletal remains. The mother of the child had retained this umbilical cord for 18 years in the child's baby book. The umbilical cord was extracted using the Qiagen EZ1 DNA Investigator Kit and, due to challenges presented by the sample type, additional steps had to be taken to ensure a successful extraction. The sample was then amplified using Promega PowerPlex Fusion 6C. A partial profile was developed with data at 20 out of 27 loci, and 13 loci showing complete data. This resulting profile was then directly compared to a DNA profile developed from recovered skeletal remains, enabling the identification of the remains.

B62 Infrared Insights: Using FTIR Spectroscopy to Predict DNA Viability in Burnt Bone Samples

Emily Jasek, BS, Sam Houston State University, Boerne, TX; Ahana Chatterjee, MS, Sam Houston State University, Huntsville, TX; Amy Z. Mundorff, PhD, University of Tennessee, Knoxville, TN; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX; Mayra Eduardoff, PhD, Sam Houston State University, Conroe, TX; Armando Anzellini, PhD, Lehigh University, Bethlehem, PA*

Learning Objectives: After attending this presentation, attendees will gain an enhanced understanding of the potential and effectiveness of spectroscopic screening techniques, specifically Fourier Transform Infrared (FTIR) spectroscopy, to assess the organic content in burnt bones samples and predict the success of DNA extraction. This knowledge will contribute to a broader appreciation of the role of non-destructive analytical techniques in forensic contexts.

Impact Statement: This presentation will impact the forensic science community by demonstrating the benefits of using Attenuated Total Reflectance (ATR) /FTIR, a widely accessible and routinely employed technique in forensic laboratories, as a predictive tool for assessing the organic content of burnt bone samples. By establishing a correlation between the spectral data obtained with ATR/FTIR and the DNA quantification data, this approach enables the estimation of the amount of recoverable and viable DNA for extraction and identification purposes. Such predictive capability can significantly inform decisions regarding sample prioritization for extraction and contribute to more effective identification efforts in forensic casework involving compromised skeletal remains.

Abstract Text: The identification of fragmentary burnt human remains in forensic investigations is primarily accomplished through DNA analysis. While effective, this process is time-consuming, costly, and particularly challenging when dealing with burned remains. In cases involving charred or calcined bone, there may be little to no recoverable DNA, yet much of the extraction and analysis workflow is frequently carried out before this determination is made. Developing a reliable pre-screening method using spectroscopic techniques, such as ATR/FTIR, could significantly streamline this process. By enabling early assessment of organic content, such a technique could help save time and resources while ensuring efforts focus on samples more likely to yield viable DNA profiles, enhancing overall efficiency of forensic identification.

A total of 33 bone samples were collected from the experimental burning of complete human cadavers at the Forensic Anthropology Center of the University of Tennessee, of which 9 exhibited thermal alteration, 10 exhibited carbonization, 10 exhibited calcination, and 4 reference samples exhibited no burning. The samples were powdered using a freezer mill for one minute, and a small portion of the powder was selected for FTIR analysis. Five replicate ATR/FTIR spectra were collected on a zinc selenide crystal using 64 scans, a spectral range of 650-4000 cm^{-1}, and a resolution of 4 cm^{-1}. The AmideI/PO_4 ratio was calculated using the area for each band. The area of the amide(I) band between 1710 cm^{-1} and 1590 cm^{-1} was calculated using a horizontal baseline, while the PO_4 band area was calculated between 1110 cm^{-1} and 940 cm^{-1} after a baseline correction between 1160 cm^{-1} and 890 cm^{-1}. DNA extracts from all samples were quantified using the Quantifiler Trio DNA Quantification Kit and correlated to the spectroscopic indices. Autosomal STR profiles were generated using the Globalfiler PCR Amplification Kit on Applied Biosystems 3500 Genetic Analyzer. Data interpretation was performed with GeneMapper ID-X Software v1.6.

ATR/FTIR spectroscopy produced well-defined spectra for all samples, consistently exhibiting characteristic absorption bands corresponding to the amide I and phosphate functional groups. The technique reliably and reproducibly indicated the presence of organic material across all 33 samples. Furthermore, the amide-to-phosphate peak ratio exhibited a strong association with the bone's organic content, with the AmideI/PO_4 index exhibiting a logarithmic correlation with the DNA quantity present in a sample, as determined through quantitative analysis. A linear regression on the log of the DNA quantification data achieved an R^2 of 0.66 and a Standard Error of the Estimate of 3.46. Above a 0.165 AmideI/PO_4 ratio threshold, 60% allele recovery was observed with a 90% likelihood. Analyzing 21 autosomal markers, this corresponds to 12 loci exhibiting no allelic dropout. Fitting a logistic regression on this correlation yielded a Positive Predictive Value of 1.00 and a sensitivity of 0.90 based on the AmideI/PO_4 ratio. This relationship suggests that the AmideI/PO_4 index can serve as a predictive indicator of DNA yield and Short Tandem Repeat (STR) typing success, providing a minimally destructive method for estimating the potential success of genetic profiling from bone material.

B63 Direct STR Amplification of Human Hair Roots

Stephanie Betts, MS, FBI Laboratory, Quantico, VA; Ivette Espinoza Quiroga, MS, FBI Laboratory, Quantico, VA; Linda Otterstatter, BS, FBI Laboratory, Quantico, VA; Joseph Donfack, PhD, FBI Laboratory, Quantico, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the DNA extraction from 4', 6-Diamidino-2-Phenylindole (DAPI) -stained human hair roots and the direct Short Tandem Repeat (STR) amplification.

Impact Statement: This presentation will impact the forensic science community by contributing to the success rate enhancement of the United States of America National DNA Index System (NDIS) -eligible STR profiles from DAPI-stained human hair roots exhibiting less than 25 visible nuclei.

Abstract Text: In a previous study, hair roots nuclei were visualized using DAPI.[1] The results showed DNA extracted from most single hair roots that contained less than 25 visible nuclei resulted in DNA yields that did not meet the target input of 1 ng recommended for STR loci amplification. Consequently, STR amplifications resulted in partial STR profiles, most of which did not meet the minimum NDIS upload eligibility requirements. This study aims to enhance the success rate of STR profiles suitable for NDIS upload or questioned to known comparison from hair samples containing less the 25 visible nuclei.

To achieve this goal, hairs were collected from five volunteers, the roots were DAPI stained, visible nuclei were counted, and the roots that contained less than 25 nuclei were selected for the study. Two DNA extraction methods were tested: a single step hair boiling DNA extraction before Polymerase Chain Reaction (PCR) (hair boil) and a full hair root immersion in the PCR buffer (hair immersion). The effectiveness of the two DNA extraction methods tested was assessed with respect to the PrepFiler Forensic DNA Extraction Kit from which STR typing results served as reference data (Reference method).

The results indicated the boil method was the most effective for which 43% of hair roots analyzed generated profiles suitable for NDIS upload compared to 19% for the hair immersion method, and 18% for the reference DNA extraction method. The boil method proposed here enhanced STR typing from single hair roots that contained less than 25 visible nuclei while complying with the guidelines or quality assurance standards because nuclei counting can be viewed as a native DNA quantitative technique.

B64 The Fundamental Principles of Activity-Level Evaluation and Their Application to a DNA Case

Simone Gittelson, PhD, The George Washington University and DC Department of Forensic Sciences, Washington, DD; Tim Kalafut, PhD, Sam Houston State University, Huntsville, TX; James M. Curran, PhD, Unversity of Auckland, Auckland, Auckland, New Zealand; John Buckleton, DSc, New Zealand Institute for Public Health and Forensic Science, Auckland, Auckland, New Zealand*

Learning Objectives: After attending this presentation, attendees will understand the fundamental principles of activity-level evaluations. They will know how to correctly formulate activity-level propositions and understand how uncertainty in the transfer mechanisms is taken into account in an activity-level evaluation.

Impact Statement: This presentation will impact the forensic science community by clarifying common misconceptions about activity-level propositions, transfer mechanisms, and their different roles in activity-level evaluations. In addition, this presentation will demonstrate how to apply these fundamental principles through a probabilistic model to a real case involving DNA recovered from under the victim's fingernails.

Abstract Text: There are many misconceptions about activity-level evaluation, specifically the separate roles held by transfer mechanisms (e.g., direct transfer, indirect transfer), the observed DNA results, and the actual activity level propositions. This talk will clarify these roles by explaining the fundamental model for activity-level evaluations. This model assigns the probability of observing the DNA result given each of two activity-level propositions and presents the ratio of these two probabilities, known in forensic science as the likelihood ratio. This model is balanced in that it considers two activity-level propositions, logical in that it has a probabilistic framework and follows the laws of probability, robust in that it uses data to assign probabilities, and transparent in that it shows the impact different variables have on the likelihood ratio through sensitivity analysis. This framework takes into account the inherent uncertainty in the transfer mechanisms by incorporating transfer probabilities, background probabilities, and contamination probabilities to assign the value of the evidence.

We apply these fundamental principles and model to an adjudicated murder case that took place in Boston, MA, to illustrate the use of this framework. In this case, DNA corresponding to a POI was found under the victim's fingernails, and the Person Of Interest (POI) stated that he had been in the victim's apartment a few weeks prior to the murder. These circumstances elevated the issue of interest to the court from sub-source level to activity level. We demonstrate a complete activity level evaluation of this case using a Bayesian network and sensitivity analysis.

B65 `Activity-Level Evaluations of Realistic Crime Scene Scenarios

Ashley Hall, PhD, University of California Davis, Davis, CA; Ray Wickenheiser, DPS*, Ray Wickenheiser Forensic Counsulting, Lafayette, LA*

Learning Objectives: In this presentation, the critical need for empirical data useful in activity-level evaluations of biological evidence will be discussed. Quantitative evaluation and DNA profiling results of DNA transferred at a realistic-scenario mock crime scene will be presented. Attendees will learn how activity-level evaluations can be supported with empirical data to benefit the trier-of-fact in deliberations.

Impact Statement: The impact to the forensic science community is rooted in the empirical evaluation of the fundamental events of DNA transfer and recovery and the metrics we can use to describe them. This expression of transfer events could contribute to activity-level evaluations of crime scene evidence.

Abstract Text: In the United States criminal justice system, juries are the finders-of-fact, and they need guidance. As the focus of biological evidence analysis shifts from identifying the DNA source to evaluating the activity by which the evidence arrived at the crime scene, it is critical that forensic scientists draw on their training, education, and experience to offer opinions that assist the finders-of-fact in their deliberations. This is especially critical when specialized knowledge is required to interpret the evidence such as in cases involving trace/touch DNA. The forensic scientist is best equipped to interpret the evidence and to address activity-level questions; if they do not, then the jury will do so themselves during deliberations.

The goal of the project was to produce empirical data informative on DNA transfer using quantification DNA recovery across a crime scene. A well-established ground truth sample containing a known quantity of DNA, the domesticated fingerprint, and its cousin the wild fingerprint, were both incorporated into experimental analysis. Two crime scenes were mocked up, one involving gunfire and the second a transfer to a knife handle. In the first, a fingerprint was transferred to a cartridge case, which was fired from a handgun. The expended cartridge case was collected for analysis and quantification of DNA transfer and recovery. In the second case, domesticated and wild fingerprints were transferred in both direct and indirect pathways, with the knife handle serving as the final surface. DNA recovery was quantified, and persistence as a contributing variable was evaluated.

Each of the pathways were repeated 20 times, producing statistically significant quantification data and DNA profiles that may be useful in activity-level evaluations. Assessments of alternate scenarios provide tremendous value when they are backed by empirical data; they may greatly aid the trier-of-fact in their deliberations.

B66 An Enhanced Recovery Method to Improve DNA Profiling Success From Handled Bullet Casings

Andria E. Morgan-Capers, BS, Virginia Commonweath University, Richmond, VA; Susan A. Greenspoon, PhD, Virginia Department of Forensic Science, Richmond, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA; Stephanie Walcott, MScFS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: After this presentation, attendees will be better informed as to which DNA extraction method might produce the best results for fired and unfired bullet casing DNA evidence.

Impact Statement: This presentation of a comparative analysis of DNA extraction methods for obtaining DNA from fired and unfired bullet casings is expected to inform the best practices in forensic laboratories and enhance the probative value of cartridge casing evidence in firearm-related investigations.

Abstract Text: The recovery of DNA from handled cartridge casings (touch DNA) from both Fired (FCC) and Unfired Casings (UCC) remains a persistent challenge in forensics due to the typically low quantity of biological material present.[1] Fired bullet casings may be the only source of DNA evidence to link a shooter to a crime scene; therefore, maximizing success with this type of evidence is crucial. This study evaluates a new DNA extraction technique, the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF) DNA laboratory's rinse-and-swab method, which incorporates a copper-chelating BTmix solution. The BTmix solution contains both Bovine Serum Albumin (BSA) and a three amino acid peptide Gly-Gly-His (GGH). BSA is a copper-chelating agent while GGH also has chelating capabilities that reduces damage to DNA by complexing copper. This new method was compared with the most common method for obtaining DNA from fired and unfired bullet casings at the Virginia Department of Forensic Science (VDFS).

The ATF protocol focuses on preventing DNA degradation from copper-induced oxidative stress by using the BTmix in a rinse solution.[2] Trace DNA from UCCs was collected through realistic handling that included donors loading and unloading the bullets with unwashed, ungloved hands into the magazine of a gun. All bullets were first soaked in DI water, scrubbed with a bristle brush and soap and water, then soaked again, followed by spraying 10% bleach and then isopropanol to remove any contaminating DNA. To collect DNA from the FCC, the bullets were loaded into a magazine and then fired. After firing, FCC were collected and placed into a chemical weigh boat to reduce DNA loss. Additionally, numerous reports have demonstrated a lower DNA typing success rate and DNA yield from brass casings versus nickel-plated.[3,4] Therefore, a comparative analysis of .357 magnum casings with nickel plating compared to a brass 9mm was performed since studies have shown that the caliber size of ammunition does not have a significant effect on the amount of DNA recovered.[5,6]

The objective of this study was to assess any improvements in DNA yield and Short Tandem Repeat (STR) profile quality for both UCC and FCC using the ATF method. The VDFS extraction method yielded an average quantitation of 0.0023ng/µL for UCC, whereas the ATF method yielded an average value of 0.0197ng/µL (same elution volumes so concentration is equivalent to yield), a nine-fold increase for nickel-plated bullets. The average yield for the VDFS FCC was 0.0027ng/µL and 0.0065ng/µL for the ATF method, more than a two-fold difference. While DNA yield for the brass UCC was 0.0057ng/µL and 0.0035ng/µL for the FCC using the ATF method, both were higher than nickel-plated UCC and FCC using the VDFS method. The profile success rate of UCC with VDFS was 45.65% while the ATF's method was 92.12% for nickel-plated and 48.64% for brass. In both cases, the ATF method yielded better results than current protocol VDFS has in place. Future experiments will focus on adapting the ATF procedure to the automated DNA purification and casework processing at VDFS.

B67 The SCAnDi Project: Single-Cell Analysis for DNA Identification

Iain Macaulay, PhD, Earlham Institute, Norwich, England, United Kingdom; Katherine Brown, PhD, University of Portsmouth, Portsmouth, England, United Kingdom; George Zouganelis, PhD, University of Derby, Derby, England, United Kingdom; Lorna Dawson, PhD, The James Hutton Institute, Aberdeen, Scotland, United Kingdom; Ardhenu Beheraa, PhD, Edge Hill University, Ormskirk, England, United Kingdom; Michael Chen, PhD, School of Engineering, University of Edinburgh, Edinburgh, Scotland, United Kingdom; Nick Dawnay, PhD, Forensic Science Research Group, Liverpool John Moores University; Liverpool, England, United Kingdom*

Learning Objectives: The attendants will be able to understand the Single-Cell Analysis for DNA Identification (SCAnDi) project's approach to single-cell isolation and DNA profiling in forensic contexts. The integration of microfluidics, imaging, and genomic workflows for analyzing individual cells will be explored while the progress made in applying these technologies to improve resolution in complex forensic samples will be recognized.

Impact Statement: The SCAnDi Project represents a transformative leap in forensic DNA analysis by applying single-cell genomics, microfluidics, and AI to resolve complex mixtures. Its impact lies in enhancing evidential clarity, enabling cell-of-origin attribution, and improving judicial outcomes. By integrating ethical frameworks and practitioner input, SCAnDi ensures real-world relevance and responsible innovation.

Abstract Text: Resolving complex DNA mixtures remains a major challenge in forensic science. Evidential samples often contain material from multiple contributors, requiring computational deconvolution of DNA profiles post-generation. This process is not always successful, which can compromise investigative and judicial outcomes by reducing evidential value.

SCAnDi is a United Kingdom-wide collaborative project that brings together leading researchers in single-cell genomics, microfluidics, AI, and forensic science to explore the applicability of single-cell technologies to forensic casework. The project aims to isolate and amplify genetic material from individual cells from mixed or low-template samples, allowing researchers to study DNA transfer, persistence, and to link cell-of-origin information with the DNA profile of the same cell.

This level of resolution could significantly improve mixture deconvolution by helping determine when, how, and by whom biological material was deposited. SCAnDi merges technical advances in cell separation and imaging with genomics workflows to target conventional Short Tandem Repeat (STR) loci using single-cell and Next Generation Sequencing (NGS) -based methods.

Commercial tools such as imaging flow cytometry alongside bespoke microfluidic platforms are employed to isolate cells prior to genomic analysis. Simultaneously, AI-based single-cell classification models are being developed to distinguish cell types—such as sperm and different sources of epithelial cells—using imaging data obtained during sorting. This aims to enable reliable attribution of the DNA profile to its biological source.

The project was selected from the UKRI Sandpit in Forensic Science for the Justice System and launched in April 2024. Stakeholder engagement was and still is central to SCAnDi's framework, with contributions from forensic practitioners, legal experts, and commercial suppliers helping shape real-world relevance and ethical implementation.

This presentation will provide an overview of SCAnDi's objectives, methodologies, and collaborative structure, highlighting progress and anticipated impact on forensic interpretation and criminal justice outcomes.

B68 Continued Optimization of a High-Resolution Melt-Based Mixture Screening Tool and Evaluation as a Contributor Identification Tool

Kiersten A. Fultz, BS, VCU Department of Forensic Science, Weyers Cave, VA; Tracey Dawson Green, PhD, Dept of Forensic Science, Virginia Commonwealth University, Richmond, VA; Chastyn J. Smith, PhD, Defense Intelligence Agency, Charlottesville, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the challenges regarding forensic sample interpretation and how the integrated Quantifiler Trio-HRM screening assay is a promising tool that can be completed during the quantification step of the DNA workflow in order to assess the potential number of contributors or genotype of a sample, allowing for proactive decisions to be made regarding sample treatment before profile generation.

Impact Statement: This presentation will impact the forensic science community by introducing an optimized screening tool that provides additional information about forensic biological samples during the quantitation step of the DNA workflow, allowing for proactive choices to be made regarding sample input and preparation. The integrated Quantifiler Trio-HRM screening assay is designed to provide objective predictions for each sample, including predictions for contributor status, number of contributors in mixtures, and two-locus Short Tandem Repeat (STR) genotyping for single-source samples. This tool allows for preliminary information to be obtained before an STR profile is generated, which can allow the analyst to make preemptive decisions about sample processing, potentially easing the complexity of subsequent profile interpretation. Adding this tool into the forensic workflow can result in more available data, potentially saving analysts time and money, limiting the need for reprocessing convoluted samples.

Abstract Text: The interpretation and analysis of forensic biological samples is currently performed at the end of the DNA workflow and requires an STR profile for loci to be assessed.[1] As DNA processing techniques become more sensitive, samples containing lower amounts of trace DNA are able to be processed through this workflow.[2] Unfortunately, sometimes trace samples contain minor contributors with low-copy DNA that result in alleles failing to pass the analytical threshold, causing convolution during analysis. This research aims to optimize a screening assay and statistical model that uses High-Resolution Melt (HRM) curve data to make predictions regarding whether a DNA sample is from a single contributor or multiple individuals. The integrated Quantifiler Trio-HRM assay adds an amplification of two STR loci to the quantification step of the DNA workflow, which provides HRM curves of approximately 2,000 datapoints for each sample. The data collected from the melt curves is analyzed using Rstudio and machine learning algorithms to make predictions regarding the contributor status of each sample.[3] The resulting predictions can aid in the decisions made before STR amplification and capillary electrophoresis are performed such as combining two samples collected from the same source that have the same single source genotype prediction or increasing the DNA input for amplification of a sample predicted as a mixture in order to bring all minor contributors above threshold for easier interpretation.

For this study, datasets containing HRM data collected from genotyped buccal swab samples were processed through a statistical prediction algorithm based on three models: linear discriminant analysis, Support Vector Machine (SVM) -radial, and SVM-linear, which then produced prediction outputs for each validation (unknown) sample. Various training and validation sets were created to assess the accuracy and reproducibility of the assay as well as its ability to accurately predict the genotype or Number Of Contributors (NOC) in samples predicted as single source or mixture, respectively.

When training sets from two loci, each containing approximately 350 melt curves, were used to train the models, 75.00% of the 72 validation set samples were accurately predicted using an 8-category labeling method (7 unique genotypes + mixtures). When genotype labels were changed to “single source” for a 2-category prediction method (single source + mixtures), overall accuracy increased to 81.94%. After increasing the number of mixtures in the training sets so that the ratio of single source and mixture samples was more evenly distributed, the 2-category dataset’s accuracy further increased to 83.30%. These results led to a final assay that uses the 2-category method for prediction modeling. The assay was 63.20% accurate in predicting the NOC in mixtures ranging from two to six contributors, with 96.00% of two-person mixtures being predicted as such. The accuracies of the three-, four-, five-, and six-person mixtures were 44.00%, 64.00%, 40.00%, and 72.00%, respectively. The inter-analyst reproducibility of the finalized assay was 66.60% and the intra-analyst reproducibility was 62.50%.

This research demonstrated the stability, robustness, and limitations of the integrated Quantifiler Trio-HRM assay and its potential for incorporation into the forensic DNA workflow for preliminary sample assessment and interpretation.

B69 When the DNA Doesn't Match the Timeline: The Annie Le Homicide and the Forensic Challenges of Unexpected DNA in Unexpected Places

Eric Carita, MS, Ace Forensic Consulting Services LLC, North Grosvenordale, CT; Peter Valentin, PhD*, University of New Haven, West Haven, CT*

Learning Objectives: This presentation will explore the high-profile 2009 homicide of Yale graduate student Annie Le, whose body was discovered hidden inside a wall at the university's Animal Research Center. DNA evidence from the scene led to the arrest of her lab technician, Raymond Clark III, but also revealed an unexpected Combined DNA Index System (CODIS) hit to a person who had been murdered two years earlier. Their DNA was found on Le's underwear, the lab gloves she was still wearing, and in multiple locations throughout the chase entrance door, interior frame, casing, and interior vent cap. This confusing result prompted a large, multi-agency investigation that lasted several months, with hundreds of hours spent examining every possible scenario that could scientifically explain how the DNA ended up there.

Impact Statement: The unexpected CODIS hit in the Annie Le case highlights the importance of maintaining high standards of competence in contamination control and evaluating case-specific hypotheses, particularly at a time when there are more questions about how the DNA was transferred to the surface where it was recovered. As cases become more nuanced and media attention intensifies, scientists must be prepared to defend their findings under heightened scrutiny, which directly impacts performance expectations and professional accountability.

Abstract Text: On September 8, 2009, Yale graduate student Annie Le was reported missing by her roommate, who observed that she had not returned after conducting her research at Yale's Animal Research Center. A large-scale search involving federal, state, local, and university police was launched, with the Connecticut State Police Major Crime Squad eventually taking over the investigation. After an extensive search of the 25,000-square-foot laboratory, Annie Le's body was found on September 13, the day she was supposed to get married. Her body was discovered upside down, having been pushed headfirst through a mechanical chase behind a toilet. This was one of the many incredibly unusual aspects to this case that now makes it relevant again with the emergence of DNA activity level propositions in casework.

On September 17, 2009, her lab technician, Raymond Clark III, was arrested and charged with her murder. The case attracted international media attention, and hundreds of pieces of evidence were submitted to the Connecticut State Forensic Lab for expedited analysis, including both serological and DNA testing. Once Le's body was extricated from the wall, swabs were taken from her body and clothing, the interior of the wall, the chase entry point, and the laboratory space shared by Le and Clark.

Additional samples were taken from her underwear and maxipad, which had been wrapped around a vent pipe in the wall, the gloves still on her hands, a bloody lab coat, a green pen found underneath her body, a bloody sock hidden above some ceiling tiles, and multiple surfaces on the entrance and interior of the chase.

DNA testing revealed an unknown male ID+/PPY profile on several key items, including Le's underwear, her gloves, and at multiple locations at the chase entrance, door frame, casing, and interior vent cap. One month after Clark's arrest, the ID+ autosomal DNA profile was submitted to CODIS, resulting in a hit to a convicted offender. After a brief investigation, it was discovered that the unknown male had been the victim of a homicide outside a bar in New Haven nearly two years earlier.

This unexpected discovery launched an extensive, multi-agency investigation focused on a single, baffling question: how could the DNA profile of a man who had been dead for years appear on Annie Le's body? Over the course of several months, investigators spent hundreds of hours exploring every scientifically plausible explanation. They examined possibilities ranging from a misidentification of the deceased individual to the existence of an identical twin or biological relative, as well as scenarios involving laboratory contamination or secondary DNA transfer. Only after systematically ruling out each hypothesis through scientific evaluation was the mystery of the DNA's presence definitively resolved.

B70 Lessons Learned in Implementing and Validating Probabilistic Genotyping

R. Austin Hicklin, PhD, Noblis, Reston, VA; Nicole M. Richetelli, PhD*, Noblis, Reston, VA*

Learning Objectives: This presentation will present findings from a project collecting lessons learned and recommendations regarding the implementation and validation of Probabilistic Genotyping (ProbGen) systems from agencies that have implemented (or are in the process of implementing) ProbGen systems. By attending this presentation, attendees will learn about issues involved in the implementation and validation of ProbGen systems.

Impact Statement: This presentation will communicate lessons learned and recommendations regarding the implementation and validation of ProbGen systems. These results may be used by laboratory management and practitioners to ease the process of acquiring, validating, and revalidating ProbGen systems. More broadly, these results may be used by laboratories and the forensic DNA community to assist in decision making, improving procedures and training, and highlighting areas for potential standardization.

Abstract Text: This lecture will be the first public presentation of the results of a study collecting best practices on adopting ProbGen systems for evaluating complex DNA mixtures. Despite the advancements and improvements offered by ProbGen systems for the interpretation of complex DNA mixtures, implementing and validating ProbGen systems is a burden for forensic labs as is the need to revalidate when procedures or settings are changed. The process of implementing and (re)validating ProbGen systems is not straightforward and requires a variety of technical and procedural decisions. The primary purpose of this project is to provide actionable recommendations—developed through collaboration and communication with the ProbGen community—that can be used by the ProbGen community and standards organizations to simplify the adoption, validation, and revalidation of ProbGen systems.

This study involved the gathering of information from a broad range of United States state, local, and private laboratories as well as from ProbGen vendors, standards bodies, forensic organizations, and relevant subject matter experts. Individual listening sessions have been conducted with each laboratory's technical leader, along with (when available) validation leads, quality managers, or laboratory directors. These sessions have focused on lessons learned and recommendations related to ProbGen implementation and validation, including acquisition, selection of settings, developing and modifying policies and procedures, validation, training of technical staff, training for end users (law enforcement and legal), adoption into operational use, transition from pre-ProbGen approaches, reporting, maintenance, and revalidation. Given that most laboratories have already implemented ProbGen but all laboratories have to address the burden of revalidation, the study is particularly focusing on lessons learned and recommendations specific to easing the revalidation process.

This lecture will provide a summary of the results and findings of the study, which will be published as a freely distributed National Institute of Justice (NIJ) report. Every effort is being made so that the resulting report will be as actionable as possible, focused on assisting forensic science service providers implementing, validating, or revalidating ProbGen systems. In order to report these recommendations as objectively as possible, recommendations are being re-circulated among the participating labs to assess the extent of consensus for each recommendation across the ProbGen community. Lessons learned collected from labs include detailed recommendations regarding what worked well; what was a waste of time, effort, or money or could have been done more efficiently; things that should have been done differently, problems and barriers; areas where coordination with other labs or forensic organizations was (or would have been) beneficial; and areas in which existing standards could be enhanced.

This project is being conducted by Noblis and funded by the National Institute of Justice (Grant # 15PNIJ-24-GG-03877-NIJB).

B71 Turning Unsearchable Mixtures Into Actionable Intelligence for Reliable DNA Evidence

Edward Schikel, MBA, Montgomery County Detective Bureau, Norristown, PA; Terrance Lewis, MA, Montgomery County Detective Bureau, Norristown, PA; Mark W. Perlin, MD, PhD*, Cybergenetics, Pittsburgh, PA; Matthew Legler, BS, Cybergenetics, Pittsburgh, PA*

Learning Objectives: Attendees will learn how Probabilistic Genotyping (PG) using the TrueAllele Investigative Database (TAID) converts unsearchable DNA mixtures into actionable investigative leads for volume crime cases. They will gain insight into how combining rapid batch testing with automated TAID accelerates intelligence development and strengthens cross-jurisdictional linkages and bolsters court-ready casework. Finally, they will understand how early DNA identification using TAID can disrupt criminal trajectories before they escalate into more serious and violent offenses.

Impact Statement: This approach demonstrates that combining traditional batch (high-throughput) DNA processing with TAID probabilistic genotyping transforms previously unsearchable mixtures into actionable intelligence, achieving faster turnaround times that accelerate case resolutions. By generating early, evidence-based investigative leads through TAID, this model supports timely interventions, disrupts escalating criminal behavior, and improves public safety at scale.

Abstract Text: Volume Crime (VC) such as burglary, gun possession, and vehicle or other property theft is more common than violent offenses but less often detected. Twenty-five years ago, the United Kingdom pioneered the application of high-speed low-cost DNA databases to VC, thereby increasing detection, interrupting criminal careers, and converting leads into evidence. Cybergenetics TrueAllele software helped distinguish simple profiles from less interpretable mixtures.

Today in America, the private sector addresses VC through local DNA databases. BodeHITS high-throughput services offer investigators higher speed 30-day laboratory turnaround at lower cost than custom casework. However, the speed tradeoff deemphasizes DNA interpretation, leaving unsearchable mixtures that yield no information.

Cybergenetics invented TrueAllele PG 25 years ago.[1] The technology uses Bayesian probability to mathematically separate genotypes from DNA mixture data, one for each contributor. Comparing inferred evidence or reference genotypes produces a Likelihood Ratio (LR) match statistic that measures DNA association strength.[2]

The TAID integrates BodeHITS DNA item data with fully automated, computer-driven, high-throughput mixture interpretation. All inferred genotypes are automatically uploaded to a DNA database that conducts ongoing LR-based matching.[3] The TAID is ideally suited for VC. Accurate and informative DNA data interpretation overcomes “unsearchable” mixtures, while parallel computing provides fast results at low cost.

Crime investigators at Pennsylvania's Montgomery County District Attorney’s Office use BodeHITS to solve property crime. They also use RapidHIT ID to develop reference DNA profiles on site. The investigators wanted to convert their many unsearchable mixtures into more investigative leads. The county began a pilot project with Cybergenetics to explore the use of TrueAllele automated genotyping and its LR-matching database with their BodeHIT system and RapidHIT instrument.

In this study, Cybergenetics examined 1,234 Montgomery BodeHIT evidence items collected over three years. The TAID match yield was 1.32 evidence-to-evidence matches per item. The TAID found 98% of the Bode items had an expected LR value over a thousand, with 75% exceeding a million. Sixty percent of the BodeHIT evidence items were not searchable; the TAID matched 72% of those mixtures.

When Montgomery requests a VC case report, within days Cybergenetics converts the TAID hit into court-ready evidence. A TrueAllele analyst reruns the evidence data four times, duplicating two different contributor assumptions. They report genotype match averages.

The TAID helps resolve weapons cases. Handgun evidence typically contains four to six contributors. Since TrueAllele reliably solves DNA mixtures containing up to ten contributors, it is useful for these VC cases.[4] The TAID’s supplemental evidence information is aiding VC investigations. In one car theft, the TAID expanded an initial BodeHIT suspect match to six additional crime scenes. The new match information can uncover criminal career progression—from property crime to gun possession to violent crime. The TAID suspect detection enables earlier intervention to divert criminals and improve public safety. Previously unsolved volume crimes are now leading to DNA-informed arrests and guilty pleas. Better forensic DNA science informs better criminal justice.

B72 Understanding and Reducing Variability in Complex DNA Mixture Interpretation: The Center of Forensic Sciences Strategic Mixture Review

Kelly A. Bowie, MSc, Centre of Forensic Sciences, Toronto, Ontario, Canada; Tanis Gornall, MS, Centre of Forensic Sciences, Toronto, Ontario, Canada; Michael Bissonnette, MS, Centre of Forensic Sciences, Toronto, Ontario, Canada; Sonja Stadler, PhD, Centre of Forensic Sciences, Toronto, Ontario, Canada; Melanie Richard, MSc, Centre of Forensic Sciences, Toronto, Ontario, Canada*

Learning Objectives: This presentation aims to provide attendees with an overview of, and improvements resulting from, the Strategic Mixture Review. This review provides insight into an engaging means of compiling and evaluating casework data for assessment and reduction of variability in complex DNA mixture interpretation approach, following adoption of Probabilistic Genotyping (PG) software.

Impact Statement: This presentation will impact the forensic community by providing a means of improving inter- and intra-laboratory consistency in mixture interpretation through lessons learned in a structured review focused on continuous improvement.

Abstract Text: The introduction of PG software presented a fundamental shift toward reporting on more complex (three or more person) DNA mixtures in our laboratory. Centered around a lens of continuous improvement and addressing the President's Council of Advisors on Science and Technology (PCAST) Report and the National Institute of Standards and Technology (NIST) Foundational Review, the Strategic Mixture Review (SMR) was undertaken five years after our implementation of STRmix into casework.[1,2] It evaluated the nature of complex DNA mixtures in our laboratory, variability in interpretation approach between scientists and whether the interpretation aligned with rationale for item acceptance the purpose of testing the item.

A review of 379 complex mixtures cataloged the interpretation strategy—manual, PG, or not interpreted—with a particular focus on variability in how scientists approached and documented decisions and whether they were suitable to achieve the purpose of testing. Factors considered included number of contributors, suitability of low-level contributors for comparison to knowns, and the noted justifications.

The purpose of testing was achieved in 80% of interpreted complex mixtures, with the most common being development of a DNA profile for upload to the National DNA Data Bank. The area of greatest variability was in the assessment of low-level contributors, with ~57% mixtures interpreted using PG having at least one component deemed not suitable for comparison. The reasons provided for these determinations revealed that the assessment of number of contributors in mixtures with low-level donors and the suitability of those contributors required further study and guidance within our scientist group.

Complex mixture interpretation exercises were designed and conducted to facilitate greater conversations and understanding of areas of variability in casework approach and sources of uncertainty in number of contributor assessment using ground truth known mixtures. Participation in the DNAmix 2021 interlaboratory study provided further opportunities to measure against a blind dataset.[3-5] STRmix validation data was further reviewed and analyzed to address concerns raised by scientists around our factor space coverage.[2] As a result of scientist engagement, DBLR Explore Deconvolution was internally validated to provide an objective data-driven means of evaluating low-level mixture components for informative value.

While the SMR gave confidence in our current application of PG, by reviewing casework and validation data with scientist engagement, it provided a constructive means of identifying areas of variability in casework approach and mixture interpretation, identifying areas for improvement in procedures and guidance to reporting scientists. Recommendations were made in the areas of purpose of testing, assessment of number of contributors, assessment of suitability of mixture components, including implementation of DBLR software, new report wording, and ongoing mixture review sessions for continuous learning and development. This has resulted in improved consistency, transparency, and clarity of the interpretation and reporting of complex mixture profiles by our laboratory.

B73 Why Not Ys? Probabilistic Interpretation of Y-STRs

Jo-Anne Bright, PhD, New Zealand Institute for Public Health and Forensic Science, Auckland, Auckland, New Zealand; Emma S. Marie, MSc, New Zealand Institute for Public Health and Forensic Science, Auckland, Auckland, New Zealand; John S. Buckleton, DSc, New Zealand Institute for Public Health and Forensic Science, Auckland, Auckland, New Zealand; Paul Stafford-Allen, BSc, New Zealand Institute for Public Health and Forensic Science, Auckland, Auckland, New Zealand; Hannah Kelly, PhD, New Zealand Institute for Public Health and Forensic Science, Auckland, Auckland, New Zealand*

Learning Objectives: We aim to present the results of a sensitivity and specificity analysis of a probabilistic genotyping method for the interpretation of Y-chromosomal Short Tandem Repeat (Y-STR) profiles. We will present some results of Y-STR mixtures deconvoluted using published biological models and discuss the typical likelihood ratios assigned using a probabilistic genotyping solution.

Impact Statement: This presentation will provide the community with an introduction to models for the assignment of match statistics for Y-STR profiles and demonstrate the performance of a possible probabilistic genotyping solution for the interpretation of mixtures generated using this technology.

Abstract Text: The interpretation of autosomal STR profiles using Probabilistic Genotyping (PG) methods is now the most common method of profile interpretation used within forensic DNA laboratories in the United States. In contrast, the interpretation of Y-STR profiles remains largely a manual process, often relying on database comparison and counting methods. A key advantage of Y-STR technology is its ability to target male-specific DNA in mixtures, particularly in sexual assault cases involving a high background of female DNA or in other cases where the male contribution to a profile is limited.

Despite its utility, the interpretation of Y-STR data presents unique challenges, especially in complex mixtures with multiple male contributors. The lack of consensus-driven interpretation frameworks, combined with varying practices for handling stochastic effects, peak height imbalance, and multi-copy loci, contributes to inconsistency and subjectivity in casework.

This presentation explores the development of a probabilistic genotyping method for the interpretation of Y-STR profiles. We will discuss the modeling of artifactual peaks, including stutter, peak height variance, and the treatment of multi-copy loci. We will also provide early results of a sensitivity and specificity studies for a range of mixtures of varying quality and quantity, and review the assigned likelihood ratios. We will discuss developmental validation considerations for the proposed method, drawing from guidance documents such as those prepared by Scientific Working Group on DNA Analysis Methods (SWGDAM), in order to provide a more transparent, consistent, and scalable approach to Y-STR interpretation

B74 A New Resource for Reporting DNA Limitations From the Human Forensic Biology Subcommittee of the OSAC

Jarrah R. Kennedy, MS, Texas Forensic Science Commission, Kansas City, MO; Michelle Madrid, MS*, Promega Corporation, Glendale, CA*

Learning Objectives: This presentation will: (1) introduce the audience to the Human Forensic Biology Subcommittee of the Organization of Scientific Area Committees (OSAC) and the work products they generate; (2) discuss the structure and contents publication of OSAC Technical Guidance Document 009: DNA Reporting Appendix Exemplar; and (3) educate the audience on the importance of including DNA reporting limitations for the readers of their reports.

Impact Statement: Attendees will leave the presentation with knowledge and understanding of a new document resource from the Human Forensic Biology Subcommittee of the OSAC, that is not a standard or best practice recommendation. The DNA reporting appendix, with a table of contents organized by the DNA process, should serve as a springboard for developing and implementing limitations statements into DNA reports that contain Short Tandem Repeat (STR) and Y-chromosomal Short Tandem Repeat (Y-STR) results and comparisons.

Abstract Text: The power of modern DNA testing to help address the "who" questions is well understood; however, its inherent limitations are not always understood by end users and these limitations may not be present in DNA reports. This lack of clarity can lead to profound misunderstandings of DNA results and comparisons by investigators and lawyers.

In the spirt of transparency and to assist in the comprehension of DNA reports, the OSAC Human Forensic Biology Subcommittee has developed a technical guidance document. This is not a new standard or best practice recommendation, but rather a practical and easy to use resource designed to help laboratories implement or enhance their reporting of DNA limitations.

Recognizing that most recipients of forensic DNA reports lack a scientific or technical background, the document provides example statements for the following categories:

- Case record and discovery
- Y(male)-screening method: Extraction and Quantitation only
- Extraction
- Quantitation
- Amplification and Detection
- Interpretation and Comparison
- Statistical Analysis
- Quality Assurance and Quality Control
- Combined DNA Index System (CODIS)
- Y-STR Testing

The examples presented in the publication are meant to be a springboard, not rigid or prescriptive, enabling laboratories to develop reporting appendices that highlight common misconceptions. By explicitly stating what DNA results do not mean, these limitation statements empower end-users—especially within the criminal justice community—to truly comprehend the DNA results before them.

B75 Highlights and Lessons From the 2025 INTERPOL DNA Review

John M. Butler, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees will learn from this presentation about a recent effort that examined over 1,300 articles published in the past three years on key topics related to forensic DNA.

Impact Statement: This presentation will provide forensic DNA practitioners and researchers with an overview of key findings, implications, and recommendations from publications over the past three years to provide a back-to-basics perspective on future directions and needs for the field.

Abstract Text: Each year, thousands of scientific articles are published in numerous peer-reviewed journals covering topics of interest to the forensic science community. This ever-growing body of scientific literature becomes increasingly challenging to monitor, much less incorporate into forensic laboratory training programs. For case-working forensic scientists, understanding which research publications are most informative would be helpful, which is a primary purpose of the triennial International Criminal Police Organization (INTERPOL) reviews.

Every three years, the International Forensic Science Managers Symposium held at INTERPOL headquarters in Lyon, France, provides updates on forensic science activities around the world. Attendees hear presentations from invited experts summarizing the scientific literature published during the previous three years on such topics as digital evidence, drug analysis, firearm examination, fire debris analysis and fire investigations, fingermarks, and forensic biology and DNA. These INTERPOL reviews are then published as open-access articles in a special issue of *Forensic Science International: Synergy* .[1]

This presentation will discuss highlights from the 2023-2025 INTERPOL DNA review, how it was conducted, what was learned, and how this information can be used to inform researchers and practitioners in this active field. Key publications are covered in this summary presentation on the following topics: rapid DNA testing, law enforcement DNA databases, investigative genetic genealogy, including privacy and ethical issues, forensic biology and body fluid identification, DNA extraction and typing methods, mixture interpretation involving probabilistic genotyping software, DNA transfer studies and evaluative reporting given activity-level propositions, next-generation sequencing, DNA phenotyping, lineage markers (Y-chromosome, mitochondrial DNA, X-chromosome), new markers and approaches (such as microhaplotypes, proteomics, and microbial DNA), kinship analysis and disaster victim identification, and non-human DNA testing including wildlife forensics.

This review summarizes books and review articles published in the past three years along with more than 40 guidance documents released by various groups within the United States and around the world since the previous 2022 review.[2] Highlights from the most valuable publications in this 2023-2025 INTERPOL DNA review can help current and future forensic DNA practitioners and researchers to get back to basics through a common body of knowledge.[3]

B76 Standards Development Activities in Human Forensic Biology

Charlotte Word, PhD, Charlotte J Word, Richmond, VA; Jarrah R. Kennedy, MS*, Texas Forensic Science Commission, Kansas City, MO; Jillian Conte, PhD, Academy Standards Board, Peckville, PA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the discipline-specific standards available for implementation in the field of human forensic biology testing.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of the standards and best practice recommendations documents currently available for implementation in DNA testing laboratories. In addition, updates regarding standards development activities pertinent to human forensic biology, including serological and DNA testing, will provide information regarding future documents that will be available for implementation. It will also increase awareness regarding training, tools, and resources that support implementation and compliance monitoring as well as the ways for practitioners to assist with the standards drafting and development processes.

Abstract Text: The Organization of Scientific Area Committees for Forensic Science (OSAC) was created in 2014 to strengthen the nation's use of forensic science by promoting the use of discipline-specific standards. To achieve this goal, proposed standards and best practice recommendations documents drafted by the various OSAC subcommittees and vetted through the OSAC technical and quality review process are posted on the OSAC Registry, at which point they are available for implementation by the forensic science community. The Proposed Standards are then forwarded to Standards Developing Organizations (SDOs), such as the AAFS Academy Standards Board (ASB). In turn, the SDO process at ASB then further develops and publishes them as American National Standards Institute (ANSI) standards. ASB develops standards with the ANSI framework which includes consideration of comments, views, and objections collected during public comment periods. The OSAC also reviews standards from other organizations and recognizes them on the OSAC Registry. The OSAC Registry serves as a central repository of high-quality, consensus-based, technically sound standards.

This presentation will discuss updates related to standards development in human forensic biology and DNA testing. These include:

- The 17 ANSI/ASB-published Standards and 2 Best Practice Recommendations (18 of which are posted on the OSAC Registry)
- The 13 documents currently in development with the ASB DNA Consensus Body, which includes 4 documents available for implementation as Proposed Standards on the OSAC website
- The 10 documents currently being drafted by the Human Forensic Biology Subcommittee of OSAC
- Implementation updates on DNA documents
- Standards resources
- How to get involved

All published standards and best practice recommendations are available for immediate download at aafs.org/academy-standards-board and on the OSAC Registry website at https://www.nist.gov/osac/registry. Opportunities for supplemental training related to discipline-specific standards will be presented as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

B77 How Increasing Transparency in Casefile Documentation Strengthened a Laboratory's Quality Management System

Britton L F Morin, MSFS, Union County Prosecutor's Office Forensic Laboratory, Westfield, NJ; Jan Pappas, MS*, Union County Prosecutor's Office Forensic Laboratory, Westfield, NJ*

Learning Objectives: After attending this presentation, attendees will understand the positive impact of increasing casefile documentation on the overall quality management system at the Union County Prosecutor's Office Forensic Laboratory. As a result of implementing recommendations made by the National Institute of Standards and Technology/National Institute of Justice (NIST/NIJ) Expert Working Group (EWG) on Human Factors in Forensic DNA Interpretation and making workflow modifications in consideration of the *Smith v. Arizona* decision, the laboratory made significant changes in casefile documentation, particularly surrounding decision points in testing strategy or interpretation made by an analyst and documentation of certain results. This presentation will discuss the rationale behind the changes, lessons learned, and resulting impacts on the quality system.

Impact Statement: This presentation will impact the forensic science community by discussing the importance of transparency in forensic decision-making and the impacts on a laboratory's overall quality system. It will present a model for implementation of several recommendations presented in the EWG's report and considerations for workflows.

Abstract Text: The Union County Prosecutor's Office Forensic Laboratory analyzes physical evidence in support of criminal investigations in Union County, NJ, focusing on seized drug and forensic biology testing. As a result of the recommendations by the NIST/NIJ EWG on Human Factors in Forensic DNA Interpretation, combined with a transition to a paperless workflow, the laboratory increased the level of documentation analysts are required to include in each casefile.[1] This included: (1) documentation of sampling strategy and reasons why specific samples were selected for further processing; (2) clearly documenting which data was used to form interpretations and conclusions, such as which loci were used to determine the number of contributors to a DNA sample or identifying the peaks being used in Gas Chromatograph/Mass Spectrometry (GC/MS) data; and (3) including photographs of results of microscopic examinations such as identification of sperm cells or crystal tests used to identify controlled substances

After the *Smith v. Arizona* decision and discussion with supervisory staff at the Prosecutor's Office, the laboratory expanded documentation to include photographic results of preliminary tests, results which had previously only been noted by the analyst performing the test.[2] For example, photographs were required for color tests like phenolphthalein or Duquenois-Levine so that a technical reviewer or other analyst could come to their own independent conclusions regarding the results of the test as opposed to just a notation of a positive result by the analyst.

As a result of this increased documentation, the laboratory was able to identify areas of improvement in the quality management system. Since all of the analytical data and decision-making was included in the casefile, gaps in understanding or application of laboratory policy were identified much more easily upon technical review of the casefile. The laboratory was able to correct gaps in understanding through the corrective action process, including retraining of staff when appropriate and updating procedure manuals, and significant changes to the training program to ensure analysts were demonstrating understanding of the analytical tests at the outset. Interpretation protocols were revised to increase clarity and consistency of application by analysts, and ANSI/ASB Standard 020 was used as guidance for validation of the new protocol.[3]

Over the past two years, the quality management system has undergone substantive changes as a result of increasing the level of documentation contained within casefiles, with an overall impact of improving the clarity of protocols, the effectiveness of the training program, and the consistency of interpretations by analysts.

B78 Restoring Scientific Rigor in Forensic Science in South Africa

Antonel Olckers, PhD, DNAbiotec, Pretoria, Gauteng, South Africa*

Learning Objectives: Science matters. In South Africa, the scientific method is not always followed and erodes the scientific rigor of results submitted to court. Accountability for scientific rigor and adherence to the scientific method rests with forensic scientists. External influences may present challenges, but forensic scientists are the advocates for science and only science.

Impact Statement: When scientific rigor is ignored, the impact echoes beyond the field of forensic science and, as in South Africa, where it is eroding the trust in forensic science and impacts justice. Case studies will illustrate the urgent need for restoring scientific rigor in forensic science in South Africa.

Abstract Text: The practice of forensic science faces persistent challenges in South Africa. Numerous cases have highlighted the difficulties in fully restoring and entrenching a rigorous scientific approach within this field in the country.

Science matters. In forensic science, the practice is not merely "forensics;" it is forensic SCIENCE, thus inherently rooted in science.[1] Challenges associated with adherence to the scientific method in forensic science are not new. Over the past few decades, increasingly urgent calls have been made for the use of the scientific model. Bevel argued that, "The best model to apply as a methodology is the already proven and accepted scientific method."[2] Bell et al. (3) issued, "A call for more science in forensic science.[2] More recently, this evolution was equated to a shift where the "... long-standing 'trust the examiner' focus is being replaced by a 'trust the scientific method' focus."[4] Roux et al. defined forensic science and outlined seven fundamental principles that, among other things, clarify the implementation of the scientific method in forensic science.[1] These "...fundamental principles can offer a compass for practitioners."[5]

Consistent application of the scientific method in forensic science practice and court testimony remains a challenge in South Africa. Cases such as *State vs. Bokolo* where only the qualitative but not the quantitative data was taken into account, and *State vs. Van Breda* where DNA results were initially reported in the context of strengthening a specific narrative, offers insight into the impact when the scientific method is not followed.[6,7] In other cases, of which *State vs. Mlanga* is one example, the testimony and affidavit could not be reconciled given that the scientific method was not followed and included persistent cognitive bias.[8] In this case, the DNA results were not considered for judgement in the case. Scientific rigor includes the quality, which is often in dispute in South Africa, with accreditation of a laboratory and regulation of its personnel being logical minimal standards and solutions.[9] Quality challenges have persisted over time as evidenced by the recent judgement in *State vs. Maboishege* where the court eventually referred the judgement for possible disciplinary actions against forensic scientists.[10]

Solutions to the challenges faced in forensic science in South Africa are attainable (e.g., accreditation of laboratories, regulation of forensic scientists, training in line with global standards, transparency, awareness of cognitive bias, and adherence to the quality system of a laboratory).

Eroding scientific rigor in our vulnerable forensic science ecosystem can lead to long-lasting consequences that may be difficult to overcome. Encouragingly, a few recent South African cases demonstrate positive advancements in the appreciation and reliance on forensic scientific testimony. Although these cases in themselves will not "turn the tide," they represent an encouraging step for forensic SCIENCE in South Africa. A crucial goal for forensic scientists remains cultivating the court's understanding and appreciation of the scientific method during testimony—although not without challenges, this is essential because science matters.

B79 Single-Cell Evaluations About How Many and Who Donated to the Sperm

Catherine M. Grgicak, PhD, Rutgers University Camden, Camden, NJ; Anu J. Khandelwal, MS, Rutgers University Camden, Camden, NJ; Desmond S. Lun, PhD, Rutgers University Camden, Camden, NJ; Qhawe Bhembe, MS, Rutgers University Camden, Camden, NJ*

Learning Objectives: The attendees will learn about new probabilistic methods that evaluate single-cell sperm, which carry only half of the DNA when compared to their diploid counterparts.

Impact Statement: By using single-cell meta data, such as images, we can address questions about how many and who contributed to the sperm cells, rather than relying on cell-agnostic bulk DNA evaluations.

Abstract Text: In classic procedures, DNA is extracted while an unknown number of cells from an unknown number of contributors is mixed. What follows is the amplification of targeted sequences, which are usually of the Short Tandem Repeat (STR) varietal. The classic procedure, therefore, carries with it a significant shortcoming; knowledge about what alleles associate with what cell, and hence cell-type, is lost.

A single-cell strategy overcomes this gap by isolating and imaging cells at the front-end of the pipeline. Here, each cell is sequestered before lysis, and Polymerase Chain Reaction (PCR) reagents are added directly to the vessel to which the cell was added. What results is a set of single-cell Electropherograms (scEPGs) that are subsequently clustered into groups by virtue of their (dis-)similarity to one another. Once clustering is complete, we apply models to assert the probability we observe the data in the cluster under same and different source propositions. With previous work showing an end-to-end single-cell predictor, named Evidentiary Evaluation of Single Cells (EESCIt), faithfully clustered epithelial and blood cells according to their contributors, we extend EESCIt to consider sperm (haploid) cells that carry only half of the donor's genetic information. Notably, unlike diploid cells, sperm are not expected to render equivalent scEPGs across cells and it is for this reason we query the performance of the system to report about *how many* and *who* donated to the set of sperm scEPGs. To do this, we place common measures of forensic validity within data analytics formulations that categorize a novelty's viability to meet forensic aims. The categories of interest are that of Salience, Legitimacy and Credibility (SLC).

With Salience referring to the applicability of the novelty to meet an actor's needs, we begin by discussing what forensic actor would consider how many and who donated to the sperm relevant questions.

Regarding Legitimacy, which speaks to evaluative fairness across a broad factor space, we determined that of 33 sperm admixtures tested (2-5 sperm donors), all scEPGs were correctly clustered. When we query if EESCIt's LRs exceeded theoretical boundaries, we confirm the following expected outcomes:(1) when there is only one sperm in a cluster the LR is not more than 1/p, where p=allele frequency; (2) that $P(LR > x|H_2\text{-true}) < 1/x$ for all $x > 1$; and (3) that $P(LR < x|H_1\text{-true}) < x$ for all $x < 1$.

Regarding Credibility, which speaks to the novelty's ability to exceed current technical capability, we found that: (1) for clusters carrying as few as two sperm, LRs ranged from 5 to 18; and (2) like earlier studies on diploid cells, logLRs of sperm are large with most landing in (22-25], and were, generally, unaffected by the number of donors or whether the mixture carried a minor donor, demonstrating scEPGs are a very robust datatype. With single cell data able to Legitimately and Credibly answer questions that are Salient to forensic actors, we integrate haploid clustering and evaluations into EESCIt, and in so doing create an end-to-end probabilistic system able to address *how many* and *who* donated to the high volumes of sperm scEPGs that come of these treatments.

B80 Catch a Sperm! The Integration of STK Sperm Tracker and Immunochromatographic Tests for Simultaneous Detection of Semen and Saliva in Sexual Assault Cases

Mayaas Hassan, BA, New Jersey Institute of Technology, Clifton, NJ; Lucia Julvez Martinez, BA, NJIT, Zaragoza, Aragon, Spain; Sara C. Zapico, PhD, New Jersey Institute of Technology, Newark, NJ; Gabriela Roca, MD, PhD, SERATEC, Göttingen, Niedersachsen, Germany; Polina Khalizov, New Jersey Institute of Technology, Livingston, NJ; Jennifer C. Santos, BS, New Jersey Institute of Technology, Newark, NJ*

Learning Objectives: After attending this presentation, attendees will consider the possibility of integrating STK Sperm Tracker detection and a new type of immunochromatographic test, PAM, which simultaneously identifies semen and saliva, to clearly distinguish between these two body fluids in sexual assault cases.

Impact Statement: This presentation will impact the forensic science community by presenting for the first time an integrating protocol, to apply in different types of substrates and fabrics, to detect these two body fluids, enhancing the possibility of identifying the perpetrator and/or the victim.

Abstract Text: The detection of body fluids, particularly semen and saliva, is vital for reconstructing crime scenes, especially in sexual assault cases. Seminal fluid and saliva detection involves both presumptive and confirmatory testing. Saliva and semen can be mapped for localization applying different techniques. Among them, STK Sperm Tracker is a screening technology that enables a sharp localization of sperm traces directly on objects and/or fabrics at crime scenes and/or in the lab. It is based on a solution (for objects) or impregnated paper (for fabrics), which reacts with semen, and it is revealed by Ultraviolet (UV) light. Amylase paper can be used for saliva mapping based on an iodine-starch reaction. After this first screening, it would be possible to use other tests, like Lateral Flow Immunochromatographic (LFI) tests, based on antigen-antibody reactions. PSA LFI assays, detect the Prostate Specific Antigen (PSA) in semen. Saliva can also be detected by LFI identifying the human salivary enzyme, α-amylase. Recently, SERATEC developed the PAM Test, which simultaneously detects human PSA and α-amylase. Based on the potential encounter of these two body fluids in sexual assault crime scenes, the aim of this study was to evaluate the integration of STK Sperm Tracker screening with Amylase Paper and PAM tests for the detection of semen and saliva individually and in combination in different substrates and fabrics.

Five ul of semen, 20 ul saliva, and their combination were deposited in three types of objects: glass, plastic, and leaves; and five types of fabrics: leather, cotton white, cotton black, denim white, denim black. Twenty-four hours after deposition, object stains were sprayed with STK Sperm Tracker and after that tested for PAM. Fabric stains were exposed to STK Sperm Tracker Lab (paper) and Amylase Paper and vice versa to detect both semen and saliva, and after that tested for PAM. DNA profiling was also performed in one replicate of each group. In the first set of experiments, on the three types of objects, STK Sperm Tracker was able to clearly identify only semen stains, even in their combination with saliva stains. PAM tests detected semen and saliva alone and in combination. In the second set of experiments, on fabrics, both STK Sperm Tracker Lab and Amylase Paper distinguished between semen and saliva respectively, even when they are mixed. PAM tests results on fabrics were like the ones observed in objects, they were able to identify both semen and saliva, alone and in combination. It was possible to retrieve full DNA profiles from all groups, including a mixture of profiles on the combination of semen and saliva.

These findings highlight the value of methods to simultaneously detect various body fluids, being able to reduce sample consumption. This would lead to selectively choosing the appropriate evidence for DNA analysis to identify the perpetrator. Future research will expand on these results, assessing other body fluids and methods.

B81 The Development of a High-Throughput Automated Method to Process Sexual Assault Kits With Increased Male DNA Recovery Utilizing an Innovative Technology

Yogesh R. Prasad, PhD, Biosecure ID Limited, Macclesfield, England, United Kingdom; Hiromi Brown, PhD, InnoGenomics Technologies, New Orleans, LA; Sudhir K. Sinha, PhD, InnoGenomics Technologies,LLC, New Orleans, LA; Randy Nagy, BSc, Gentueri Inc., Middleton, WI; Sid Sinha, MBA, InnoGenomics Technologies, New Orleans, LA;Anusha Prasad, Biosecure ID Limited, Macclesfield, England, United Kingdom*

Learning Objectives: By attending the presentation, forensic scientists will learn about a new approach for automated Sexual Assault Kit (SAK) differential DNA extraction and analysis. They will understand the limitations of current methodologies for Sexual Assault Sample Kit processing, learn how the nanofiber-based differential extraction method simplifies evidence sample processing, and how positive pressure automation enhances throughput and consistency while decreasing manual processing time and plastic consumables.

Impact Statement: The forensic scientists will be able to use their knowledge gained from this presentation to include this new protocol in their regular DNA analysis of sexual assault samples through automated processing lines. Forensic laboratories can then effectively reduce SAK backlogs and increase the chances of obtaining Combined DNA Index System (CODIS) -uploadable Short Tandem Repeat (STR) DNA profiles utilizing a novel technology.

Abstract Text: Attendees of this presentation will learn about recent advances in automating differential extraction using nanofiber-based SpermX technology. The manual SpermX GenSpin device, which incorporates a nanofiber membrane into a Gentueri GenSpin basket (SpermX-GS), performs identically in recovery and performance to the original SpermX devices using an AutoLys tube as previously reported. It was reported earlier that the original SpermX method enhances sperm-derived DNA recovery by 3-5 times compared to the conventional Gill method.[1] The SpermX-GS device significantly improves sperm recovery and increases CODIS-uploadable profiles by 30% compared to alternative differential extraction methods. To improve throughput and ensure reproducibility, we present an automated version of this workflow. Using a Positive Pressure Module (PPM) and a specially designed cartridge compatible with leading automation platforms such as Tecan or Hamilton—already common in forensic laboratories—this setup enables the simultaneous processing of up to 48 sexual assault swabs. It covers all steps from differential digestion to the elution of E- and S-cell lysates, without centrifugation. The PPM replaces manual procedures with controlled air pressure, gently opening the nanofiber membrane and allowing smooth buffer exchange and incubation. Integration with liquid-handling and heating modules further reduces hands-on time and operator error, providing consistent yields across various forensic sample types.

Evaluation results will be presented to show high recovery and clean profiles (< 5% female contributor alleles) from a two-person mock epithelial-semen mixture and < 10% minor-contributor alleles when blood from a third individual is spiked into that epithelial-semen mixture (creating a three-donor mixture sample). These samples were spotted on a cotton swab and dried before processing. Introduction of the technology by a United States forensic lab has resulted in about 30% more CODIS-uploadable profiles than their previous differential extraction method for processing of SAKs.[2]

This innovation blends simplicity in manual workflows with scalability in automation, opening a path for broader adoption of nanofiber-based differential extraction in forensic labs. With crime labs facing ongoing backlogs of untested SAKs, often delaying justice by months or years, this technology provides a crucial boost in both speed and scalability, increasing the success rate of obtaining a usable Short Tandem Repeat (STR) profile from SAKs. The system is modular and compatible with standard crime lab equipment and commercially available liquid handling systems, making it suitable for high-throughput in resource-limited settings.

B82 A Proteomic Analysis of DNA Extraction and Isolation Waste: Having Your DNA Cake and Proteome Too!

Glendon J. Parker, PhD, University of California, Davis, Davis, CA; Daniella Corene C. Luistro, MSFS, University of California, Davis, Vallejo, CA; Kyle Burk, MS, UC Davis, Parker Lab, Davis, CA; Allysa Tewksbury, MSFS, California Department of Justice, Riverside, Riverside, CA; Phillip B. Danielson, PhD, University of Denver, Denver, CO; Christian Westering, PhD, Niagara County Sheriff's Office, Forensic Laboratory, Lockport, NY*

Learning Objectives: This presentation will introduce a novel approach for maximizing the forensic informational value of evidentiary samples by demonstrating that the "waste" fraction generated during DNA extraction can serve as a valuable source of proteomic information. By preserving the protein degradation byproducts typically discarded after DNA isolation, and regardless of Proteinase K (PK) use, analysts can obtain additional forensic information, such as body fluid identification, without altering their existing DNA workflows.

Impact Statement: This strategy has the potential to significantly enhance the probative value of routine DNA extractions by offering a practical and cost-effective means of integrating proteomic source analyses without requiring changes to existing laboratory workflows or DNA protocols.

Abstract Text: Protein is the major chemical component of all biological evidence. Protein denaturation or digestion is necessary to extract nucleic acids for DNA profiling. A typical assumption of investigators is that this process is incompatible with subsequent protein analyses for body fluid identification. We report two studies here that refute this assumption. First, we report that even the use of PK precludes neither the ability to obtain informative protein datasets nor the proteomic identification of semen. Second, we report that the major initial waste fraction in the DNA IQ DNA extraction protocol is a rich source of proteomic information.

In accordance with the Differex/DNA IQ protocol, semen was incubated at a 1 in 20 dilution in 4.6 mM DTT. Samples were then digested with either PK, as per the protocol, or 5µg of mass-spectrometry-grade trypsin, the latter being the standard for proteomic analysis. Relative to trypsin, the use of PK resulted in an apparent (albeit not statistically significant) decrease in the number of detected proteins from 485 ± 163 to 392 ± 164 ($p = 0.52$). Peptide levels saw virtually no change with 5,299 ± 313 compared to 5,586 ± 2,991($p = 0.88$). The use of PK did result in significantly smaller more diverse peptides, with peptide length being reduced from 18.4 ± 0.1 to 11.3 ± 0.1 residues ($P = 10^{-84}$). With PK digestion all semen markers were detected, with an increased glycodelin and decreased beta-microseminoprotein signal.

Except for hair and semen, the DNA IQ protocol does not recommend PK; relying instead on detergents and denaturants to extract DNA for capture on paramagnetic beads. This is fully compatible with proteomic suspension-trap preparative workflows. We conducted DNA isolation from four body fluids and analyzed the protein population before and after DNA had been bound to the paramagnetic beads. The proportion of protein in the initial wash was 78.8 ± 25.5% for blood, 98.5% ± 2.6% for saliva, 91.5 ± 5.6% for semen and 92.4 ± 6.3% for a semen/vaginal fluid mix. There were no changes in the quality or quality of proteomic data obtained from the initial post-bead wash, compared to the pre-bead lysate. When body fluids on cotton swabs were processed with trypsin and compared to the profile of major biomarker proteins in the discarded fraction from the DNA extraction, similar ratios were detected. The quality of the proteomic data obtained from the DNA waste fraction was uniform across all body fluid samples tested. In this study, hemoglobin in the final DNA isolate was detected at one hundred thousandth the signal from that obtained from neat blood.

This study demonstrates that the waste products from the DNA-isolation process are excellent sources of proteomic information with no significant loss from the use of paramagnetic bead-based extraction protocols. Even PK digestion is unlikely to alter the results of basic analyses. This indicates that discarding the waste fractions from DNA isolation also discards material from which body fluid identifications could be readily obtained with potential utility for source attribution.

B83 Harnessing New Enzymes to Improve Differential Extraction

Robin W. Cotton, PhD, Boston University, Boston, MA*

Learning Objectives: After attending this presentation, listeners will have a good understanding of the biological and sampling-related cell characteristics that make differential extraction a technically challenging process. Attendees will also hear a discussion of a new differential process that has the potential to improve results while decreasing processing time.

Impact Statement: This presentation will impact the forensic community by providing a detailed description of a new approach to differential extraction and illustrating results from the new method and from conventional methods.

Abstract Text: Analysis of sexual assault samples requires the effective separation of two different cell types and the subsequent lysis of both, prior to DNA extraction. The original procedure for differential extraction was invented by Gill, Jefferys, and Werrett and was published in Nature in 1985.[1] Sexual assault samples represent the majority of samples submitted to many forensic laboratories. Procedures for Y-chromosome screening, the use of DNAase to remove excess female DNA, and implementation of robotic DNA extraction methods have improved the speed and outcomes of processing sexual assault samples.

We will briefly review the biology of sperm and will show data that describe the distribution of vaginal epithelial cells and sperm cells into the e-cell and sperm cell fractions as well as the amount of each of these cell types that remain on the cotton swab. This data explains why the process is technically challenging and often does not give optimal results.

A differential extraction process will be introduced that uses a temperature-controlled procedure, two proteases, and a nuclease to effect separation of epithelial cells and sperm cells. The process does not require reducing agents. The process does not eliminate the need for centrifugation to remove sperm from lysed epithelial cells. The activity of each protease and the nuclease is controlled by temperature and the e-cell and sperm cell lysates can potentially go directly to quantitative Polymerase Chain Reaction (qPCR) and Short Tandem Repeat (STR) amplification. A description of this process, the process components, and example results will be presented.

B84 Optimizing a DNA-Based Workflow for Distinguishing Marijuana From Hemp: An Alternative to Traditional GC/MS Analysis

Rory Conn, BS, The George Washington University, Fairfax, VA; Ya-Chih (Jessica) Cheng, PhD, The George Washington University, Washington, DC; Tanya Ryzi, BS, The George Washington University, Washington, DC*

Learning Objectives: Attendees will learn how an optimized DNA-based workflow can efficiently differentiate marijuana from hemp. The presentation will explore how this method offers a fast, accurate, and cost-effective alternative to traditional chemical techniques like Gas Chromatography/Mass Spectrometry (GC/MS).

Impact Statement: The legal and chemical distinction between marijuana and hemp established by the 2018 Farm Bill resulted in an increased complexity of forensic *Cannabis sativa* analysis. This presentation introduces an optimized workflow for a previously developed Custom TaqMan Probes qPCR Assay for differentiating hemp and marijuana, featuring faster DNA extraction and a shortened protocol. The improved method enables forensic laboratories and law enforcement to process seized cannabis samples more efficiently.

Abstract Text: With the passage of the Farm Bill, the legalization of hemp (cannabis with no more than 0.3% delta-9-tetrahydrocannabinol) introduced new challenges in distinguishing it from illegal marijuana in *Cannabis sativa* analysis. Traditional chemistry methods like GC/MS remain the gold standard for differentiating hemp from marijuana, but they are time-consuming and labor-intensive. Conversely, DNA-based methods could offer higher throughput analysis, reduced sensitivity to sample type and quantity, and improved applicability to older samples, with chemical compositions that may have changed over time.

This study optimizes the workflow of a previously developed Custom TaqMan Probes qPCR assay for differentiating marijuana from hemp.[1] The original workflow included sample weighing, DNA extraction, quantitation, dilution, and quantitative Polymerase Chain Reaction (qPCR) genotyping. To improve efficiency, the current study evaluated four DNA extraction methods to reduce processing time while maintaining reliable genotypic results. The selected method was further optimized for speed and simplicity. To assess the feasibility of omitting sample weighing and DNA quantitation, the assay's upper and lower Limits Of Detection (LOD) were validated, and the range of DNA quantities obtained from the extraction was evaluated. Results indicate that analysts can visually estimate sample input, perform extraction using Chelex 100 Resin, and proceed directly to qPCR without compromising accuracy. The optimized workflow was then compared with the traditional GC/MS method, evaluating both approaches in terms of sample preparation, extraction procedures, instrument run time, and data analysis.

In summary, this presentation highlights the efficiency of the optimized DNA-based method for the differentiation of hemp and marijuana, offering a practical complement to traditional chemical methods.

B85 Tracing Time Through Touch: Fingerprints and Microbes as Temporal Tools to Date Evidence

Josep De Alcaraz-Fossoul, PhD, University of New Haven, West Haven, CT*

Learning Objectives: Attendees will learn about time-dependent microbiome-based forensic methods to generate temporal (microbial) signatures for reconstructing the timeline of criminal events. The presentation will demonstrate how microbial composition and succession within latent fingerprints reveal biopatterns to help estimate Time-since-Deposition (TsDp).

Impact Statement: This presentation will advance the forensic science community by showing preliminary evidence that microbial communities within latent fingerprints can become potential biomarkers for estimating TsDp. This microbiome-based approach may provide improved temporal resolution and individual specificity compared to 2D and 3D optical methods, potentially enhancing the accuracy of activity-level propositions.

Abstract Text: For over a decade, researchers have actively sought to decode the natural degradation, or "aging processes." of Latent Fingerprints (LFs).[1] The main goal has been to develop a methodology that could estimate TsDp, a critical step forward in evidence analysis and crime solving. While traditional friction ridge analysis identifies "who" may have touched an object, it cannot yet establish "when" and thus is unable to confirm contemporaneity between LF presence and criminal activity.

Several strategies have explored the aging processes of LFs through chemical compound analysis and topographical changes under laboratory conditions.[2] However, progress has usually been hindered by limited experimental conditions driven by financial constraints that restrict the number of variables tested. Multiple factors have been documented or hypothesized to influence LF degradation, categorized into donor conditions, substrate characteristics, and environmental variables.[3] However, their relative contributions to LF "life expectancy" remain unclear.

Among the tested methods, 2D and 3D imaging techniques have emerged as fast, easy, and accessible.[1] 3D imaging has shown promise in detecting early topographical changes in friction ridges, while 2D imaging may assess ridge clarity over longer times.[1] Still, the temporal resolution of both is limited, typically from a few days to several weeks, and combining them appears not to significantly improve accuracy, as they often represent complementary but non-overlapping timescales.

A promising and underexplored dimension lies in the microbiota present in LFs, directly transferred from skin during surface contact.[4,5] These microbes initially mirror the skin's communities, which include both core taxa (relatively stable over time and across individuals) and transient taxa (variable and more environmentally dynamic).[6] The latter has been proven to evolve dynamically over time in response to ambient conditions, and their succession may provide unique, time-dependent signatures, termed the *chronomicrobiome*, as a potential "biological clock" that could theoretically position LFs in time.[6,7]

This study investigated how LF microbiota changed over time across two unrelated individuals, considering three key variables: handedness (left vs. right), hand washing (pre- and post-washing), and elapsed time post-deposition (3, 96, and 192 hours). LFs were deposited from both hands onto glass substrates, before and after hand washing, and aged in a monitored (but not controlled) dark indoor setting. Microbial DNA was extracted at its respective times, and 16S rRNA gene sequencing was performed to characterize time-dependent microbial composition.

Preliminary results confirmed that washing hands significantly altered transient microbiota composition, introducing new taxa absent in unwashed conditions. Time-dependent community shifts were observed, with several taxa emerging or disappearing at specific intervals. This suggests that microbial succession may be both time-dependent, hand-dependent, and potentially donor-specific, supporting the hypothesis of constructing temporal (microbial) signatures for forensic TsDp estimations.

By increasing the resolution of microbial taxonomic data, incorporating intra- and inter-donor variability, and expanding environmental conditions, the *chronomicrobiome* could become a forensic instrument to help reconstruct the timeline of touch-based evidence.

B86 Utilizing Digital PCR to Track Bacterial Transfer Following Sexual Assault

Dipanwita Raha, BSc, Florida International University, Miami, FL; Andrea Ramirez-Torres, BS, FIU, Miami, FL; Bruce R. McCord, PhD, Florida International University (FIU), Miami, FL; George Duncan, PhD, Nova Southeastern University, Dania Beach, FL; Mirna Ghemrawi, PhD, The Center for Forensic Science Research and Education, Horsham, PA*

Learning Objectives: Upon attending this poster presentation, the attendees will learn about how the genital microbiome can be a great tool in sexual assault cases where little-to-no human DNA is present. Also, it will be demonstrated how we can use digital Polymerase Chain Reaction (PCR) for it's detection even if it's present in trace amounts.

Impact Statement: My presentation will help the forensic community to look at the human genital microbiome from a new angle and demonstrate the potential of digital PCR to be used in this field.

Abstract Text: Sexual assault is classified as a non-consensual sexual contact either by physical force or incapacitation. Sexual assault affects one in three women globally, while in the United States, one in four women face some form of sexual assault in their lifetime.[1,2] Investigations in these cases primarily depend on isolating perpetrator DNA from rape kits collected from the victim or the crime scene, but this process faces challenges when vaginal swabs are taken more than 24 hours post-assault or when female DNA overwhelms the sample. Differential extraction and Y-chromosomal Short Tandem Repeat (Y-STR) profiling are commonly used methods to isolate male DNA, but both have significant limitations in terms of efficiency and the potential for degradation. These challenges require improved forensic tools to aid in establishing sexual assault. We are exploring microbial forensics and digital PCR in an effort to provide novel tools for the detection of sexual assault in situations in which the recovery of human DNA is low.

The human genital microbiome offers a powerful yet underexplored avenue for such scenarios. Previous studies have shown that the microbial communities inhabiting male and female genital regions are distinct, stable, and often individualized. Female genitalia are predominantly colonized by *Lactobacillus* species such as *L. crispatus*, *L. iners*, and *L. gasseri*, whereas the male genital microbiota tends to include *Corynebacterium*, *Staphylococcus*, *Anaerococcus*, and *Prevotella* species. These microbial signatures are influenced by host physiology, hygiene, sexual activity, and anatomical factors making them biologically informative.

Microbiome transfer during sexual contact can alter the genital microbial composition between partners. Multiple studies have shown that sexually active individuals may harbor genital bacterial strains partially derived from their partners.[3,4] Detection of such microbial overlaps post-assault may provide biological evidence of sexual contact, especially in the absence of sperm or degraded human DNA. Furthermore, microbial profiles persist longer than DNA in some conditions, offering a temporal advantage in delayed reporting cases. Research by Swayambhu et al. illustrated the potential of standardized microbiome pipelines in forensic sample processing, where even dried genital swabs retain detectable microbial DNA.[5]

In our study, genital microbiome samples have been collected from volunteers, and microbial DNA have been extracted using a ZYMOBIOMICS DNA MicroPrep Kit. Specific primers and probes are being designed to target the genital-specific bacteria for a nanoplate digital PCR based assay. This assay would provide absolute quantification in copies per µL using a poisson distribution without the need for culture enrichment or direct calibration.

We are using a QIAcuity digital nanoplate system. The format of this instrument makes the system highly sensitive and resistant to PCR inhibitors. Up to 12 different amplicons specific to different vaginal and penile microbes can be multiplexed in this system. The accuracy, specificity, and sensitivity of the developed dPCR assay are assessed using established bacterial standards and the methodology is assessed using lab prepared standards and post-coitial samples.

B88 The 2026 Update From the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG)

Jaclyn Iera, PhD, DEA, Springfield, VA*

Learning Objectives: This presentation provides an overview of the most recent activities and work products of SWGDRUG over the past year and updates the audience on resources available for seized drug laboratories.

Impact Statement: The SWGDRUG supports the development of internationally accepted minimum standards for forensic examination, identifies best practices within the international community, and provides resources to help laboratories meet these standards.

Abstract Text: The SWGDRUG was formed in 1997 in a joint effort between the United States Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). The SWGDRUG works to improve the quality of the forensic examination of seized drugs and to respond to the needs of the forensic community by supporting the development of internationally accepted minimum standards, identifying best practices within the international community, and providing resources to help laboratories meet these standards. This presentation will provide attendees with information on the SWGDRUG activities during the past year and updates on resources available to the global forensic community.

The SWGDRUG core committee members met virtually in the summer of 2025 to discuss and finalize a new recommendation, Part IIIE, Methods of Analysis/Stop-Testing Procedures and Negative/Indicative Results, for a public comment period. This new section addresses a common question in seized-drug laboratories by providing a framework when relevant analytes are not conclusively identified. In addition, the SWGDRUG Sampling Sub-Committee is completing a draft on updated recommendations for when negative results are obtained during qualitative/screening analyses. Within the ongoing opioid crisis, encountering units that do not contain a consistent analyte is becoming a common occurrence in laboratories. These updated recommendations, drafted to include an example utilizing the new National Institute of Standards and Technology (NIST) Lower Confidence Bounds for Seized Material Sampling App, will provide a statistical approach and the mathematical background to handle these scenarios.

The SWGDRUG continues to engage with the public through various webinars. In January of 2025, the SWGDRUG participated in the Center for Forensic Science Research and Education's (CFSRE) Current Trends in Seized Drug Analysis Symposium. The SWGDRUG's participation was well received, and the group is again planning to participate in the 2026 CFSRE Current Trends in Seized Drug Analysis Symposium.

Future work for the committee will involve the creation of a supplemental document to support the new stop-testing procedures by providing examples of various scenarios in which the framework is applied. The SWGDRUG committee is also drafting procedures for structural elucidation and revising the currently existing Supplemental Document SD-2 (Validation of Analytical Methods). The SWGDRUG remains committed to engaging with the public and providing webinars and presentations.

This presentation will also summarize recent updates on multiple SWGDRUG resources, including two new external resources: the NIST Lower Confidence Bounds for Seized Material Sampling App and the Analytical Methods and Open Spectra (AMOS) database developed at the Environmental Protection Agency (EPA).

The SWGDRUG core committee includes representatives from regional, national, and international forensic organizations; educators, practitioner and scientists from the United States; and representatives from the European Network of Forensic Science Institutes (ENFSI), the Iberoamerican Academy of Criminalistics and Forensic Studies (AICEF), the Asian Forensic Science Network (AFSN), the Australia New Zealand Forensic Science Society (ANZFSS), the Canada Border Services Agency (CBSA), and the United Nations Office on Drugs and Crime (UNODC).

B89 Seized Drug Trends in the Northeastern United States: A Decade of Macro and Micro Trends

Tara Rossy, BS, Drug Enforcement Administration Northeast Laboratory, New York, NY*

Learning Objectives: After attending this presentation, attendees will understand the trends observed in seized drug samples spanning the past ten years in the Northeastern United States to include commonly seen drugs, New Psychoactive Substances (NPS), and adulterants.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of the substances identified in seized drug exhibits, illustrating long-term macro and micro trends in the region.

Abstract Text: Between 2015 and 2025, the Drug Enforcement Administration (DEA) Northeast Laboratory analyzed approximately 40,000 seized drug exhibits submitted from the Northeastern Region of the United States. This region encompasses Connecticut, Delaware, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont. Exhibits were submitted to the laboratory for analysis from federal, state, and local agencies. Data was compiled from exhibits analyzed at the DEA Northeast Laboratory and extracted from the Laboratory Information Management System (LIMS) to cover the period of January 1, 2015, to December 31, 2025.

At the DEA Northeast Laboratory, cocaine, fentanyl, heroin, methamphetamine, and oxycodone are consistently among the most commonly identified drugs with the ranking of these drugs changing over the past decade. The contribution of cocaine to the total makeup of substance identifications has remained fairly consistent, while the proportion of methamphetamine identifications has increased. The decline of heroin and rise of fentanyl is the most significant change observed during this ten-year period. Heroin was the most commonly identified drug in the Northeast Region of the United States in 2015. However, beginning in 2020, fentanyl replaced heroin as the most commonly identified drug.

While the identities of the top five analyzed drugs remain consistent, the emergence of synthetic cathinones, synthetic cannabinoids, fentanyl-related compounds, benzodiazepines, and nitazenes have provided an ever-changing landscape of compounds to identify. Micro trends have become more frequent as law enforcement agencies and governments work to combat the newly emerging compounds. While some compounds persist over the years (e.g. *para*-fluorofentanyl), other compounds are identified numerous times in one year and subsequently disappear (e.g., APP-CHMINACA). Substances such as carfentanil may not be seen often, but instances of identification are notable due to their potency. The progressive increase in identifications of carfentanil should be monitored to inform future enforcement actions, policy, legislation, and public health efforts. Adulterants, such as xylazine, were seen infrequently in the past and are now consistently identified. When enforcement efforts targeted xylazine in 2024, an increase in medetomidine, a substance used for similar veterinary indications, was observed. Studying this trend in the future can determine if medetomidine is being utilized as an alternative to xylazine.

Forensic laboratories routinely encounter these NPS and adulterants, which provide unique challenges in the field of seized drug analysis. Understanding trends can assist both analysts in overcoming analytical challenges and public health officials in taking steps to mitigate substance use.

B90 ATR/FTIR and Raman Hyperspectral Imaging With Chemometric Modeling for the Detection of Xylazine in Illicit Drug Mixtures

Xuyang He, PhD, The University of Southern Mississippi, Hattiesburg, MS*

Learning Objectives: After attending this presentation, attendees will gain: (1) an understanding of sample preparation-free, label-free, and reference-free identification of key components of drug mixtures of interest; (2) insight into how specific chemometric methods can deconvolute complex spectra and semi-quantify toxic adulterants; and (3) awareness of the forensic and public health significance of analyzing xylazine in seized drug evidence.

Impact Statement: This work presents a rapid, non-destructive method for detecting xylazine and other drug adulterants, providing forensic laboratories with a powerful tool to enhance the analysis of seized drugs. Its broader implications include improved public health monitoring and stronger law enforcement capabilities to address the rise of illicit drug adulteration.

Abstract Text: Xylazine, a non-opioid veterinary tranquilizer, has increasingly been identified as a toxic adulterant in illicit opioids, raising public health concerns due to its potent sedative effects and resistance to opioid antagonists like naloxone.[1,2] Detecting xylazine in seized drug samples is essential for forensic casework and public health surveillance. However, traditional immunoassays suffer from cross-reactivity, while Gas Chromatograph/Mass Spectrometry (GC/MS) requires time-consuming sample preparation and destructive analysis, highlighting the need for rapid, reliable, and non-destructive alternatives.

This study introduces two complementary vibrational spectroscopy approaches, combined with chemometric methods, for identifying xylazine in complex drug mixtures: Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) spectroscopy with Principal Component Analysis and Linear Discriminant Analysis (PCA-LDA), and Raman hyperspectral imaging coupled with Multivariate Curve Resolution–Alternating Least Squares (MCR-ALS).[3,4]

Powder drug mixtures containing varied amounts of xylazine were analyzed using both workflows. PCA reduced the dimensionality of IR spectra, while LDA effectively classified adulterated versus non-adulterated samples. Raman imaging combined with MCR-ALS enabled deconvolution of overlapping spectral signatures, recovery of pure component profiles, and estimation of relative concentrations. The performance of this method was validated by a high Pearson correlation between deconvoluted and reference spectra, and by percent variance explained for xylazine contributions.[5]

These results highlight the value of combining vibrational spectroscopies with chemometric modeling for the streamlined analysis of complex drug mixtures. This dual-platform strategy eliminates the need for standards, labeling, or sample preparation, and provides forensic laboratories with a practical alternative to conventional methods for monitoring emerging adulterants like xylazine in seized drug evidence.

B91 Multi-Drug Quantification by LC/MS/MS: Overcoming Enhancement and Suppression

Joshua S. DeBord, PhD, Center for Forensic Science Research & Education, Horsham, PA; Max T. Denn, MS, CFSRE, Horsham, PA; Barry K. Logan, PhD, Center for Forensic Science Research & Education, Horsham, PA; Alex J. Krotulski, PhD, Center for Forensic Science Research & Education, Horsham, PA*

Learning Objectives: Attendees will gain an appreciation for practical challenges encountered during the development of a multi-analyte quantification method of drug materials, with a specific focus on identifying and mitigating ionization enhancement and suppression effects unique to complex drug mixtures. The presentation will describe the experiments used to evaluate these effects as well as corrective measures that ultimately led to an optimized method. This overview will provide insights into method development and validation for quantitative analytical drug chemistry.

Impact Statement: This work highlights the critical importance of addressing ionization effects in multi-analyte quantification workflows, especially in the context of complex mixture samples that are increasingly common in drug-related casework. By sharing the setbacks and strategies used to overcome these issues, this presentation provides guidance for other forensic laboratories facing similar challenges.

Abstract Text: Drug quantification in seized drug and public health surveillance/drug checking is key to understanding changes in drug markets, and the potential toxicity of illicit drug products at the point of distribution or sale. Developing a multi-analyte quantification method for drugs, precursors, and adulterants is a critical yet complex task in forensic analytical science. This presentation details the development and validation of a Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method designed to quantify multiple drugs and adulterants within drug material samples (e.g., pills, powders, tablets).

The method was designed to quantify 4-ANPP, cocaine, diphenhydramine, fentanyl, fluorofentanyl, heroin, ketamine, levamisole, lidocaine, MDMA, medetomidine, methamphetamine, phenacetin, procaine, quinine, tetracaine, tramadol and xylazine at mass concentrations between 1% - 100% as a standard protocol, although dilutions can be adjusted to quantify analytes < 1%. For the chromatography a Waters HSST3, C18 column was used with a concave mobile phase gradient from 85% of 0.1% formic acid in H2O (A) to 95% of 0.1% formic acid in methanol (B) over 3 minutes. The total runtime with equilibration was 5 minutes. Mass spectral identification was performed with multiple reaction monitoring of two required transitions per analyte with acceptable diagnostic ion ratios.

Early in method development, results were encouraging for the use of a surrogate internal standard, zolpidem-d7, being used for all analytes in the method. However, a pivotal challenge emerged in the form of enhancement and suppression effects that were only evident when analytes were tested individually or in simpler mixtures. For example, using the multi-component calibrators and surrogate internal standard, casework samples containing only cocaine had calculated concentrations between 130 – 150%. We concluded that analyte-specific interactions led to variability in analyte response, compromising quantitation accuracy and method reliability. To address these issues, process efficiency studies and matrix effect evaluations were employed to identify problematic interactions and propose mitigation strategies, which included selecting stable isotope-labelled internal standards for analytes, or the re-assignment of surrogate internal standards for analytes without corresponding isotope-labeled internal standards. Accordingly, using cocaine-d3 as the internal standard for cocaine compensates for differences in ionization that occurs in complex mixtures of analytes compared to samples containing only one or a few analytes.

In addition to a discussion of the validation results, this presentation will provide attendees with an understanding of both the scientific challenges and practical considerations involved in developing quantitative methods for complex drug mixtures, highlighting the importance of systematic validation when scaling up from a single analyte or simple panel to an assay involving many analytes. This experience highlights the need for comprehensive/thorough validation, even when methods appear to perform well under simplified conditions and challenging the method with more realistic samples analogous to those encountered in casework. Confronting these challenges encourages transparency in forensic method development and supports the reliability of the method.

B92 `A Method Development for Ultraviolet Absorbance and Fluorescence Detection of Psilocybin and Psilocin Following Liquid Chromatographic Separation

George N. Sakellariou, BS, The George Washington University, Washington, DC; Walter B. Wilson, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Ya-Chih (Jessica) Cheng, PhD, The George Washington University, Washington, DC*

Learning Objectives: After attending this presentation, attendees will learn about a novel approach to detecting and quantifying psilocybin, psilocin, and other related compounds using Liquid Chromatography/Photodiode Array (LC/PDA) and Liquid Chromatography/Fluorescence (LC/FL).

Impact Statement: This presentation will encourage forensic practitioners to explore the use of LC to separate psilocybin and psilocin in psychedelic mushrooms and edibles. Practitioners will also learn how to quantify these analytes using absorbance and fluorescence detection.

Abstract Text: Psilocybin and psilocin were defined by the Controlled Substances Act of 1970 as Schedule I controlled substances in the United States. These psychoactive compounds are found in hallucinogenic "magic mushrooms" of the *Psilocybe* genus. Unlike the legislation surrounding *Cannabis*, there are no legal protections related to the percent composition of psilocybin and psilocin in seized drugs. While Colorado and Oregon have since decriminalized the use of psilocybin and psilocin, the drugs remain federally illegal, which stresses the need for continued method development for implementation into forensic laboratories.

Gas Chromatography (GC) is widely considered the "gold standard" for the analysis of seized drugs in forensic laboratories. However, the chemical and physical properties of psilocybin make this type of analysis difficult. In aqueous standards, psilocybin is photosensitive and oxidizes in contact with air and light.[1] Additionally, psilocybin's poor volatility and thermal lability lead to dephosphorylation in the GC inlet, which will produce psilocin.[1,2] For this reason, LC with various detection methods such as Ultraviolet (UV) absorbance, Fluorescence (FL), Mass Spectrometry (MS), and Tandem Mass Spectrometry (MS/MS) is a far more favorable tool for psilocybin detection and quantification.

The Chemical Sciences Division at the National Institute of Standards and Technology had previously developed an LC-UV method for the analysis of 11 cannabinoids in *Cannabis* plant samples.[3] Considering the current implementation of this method in forensic laboratories, the present study evaluates similar conditions for the detection of psilocybin and psilocin. The results presented here will demonstrate the use of a 100% water (H2O) with 0.085% phosphoric acid mobile phase and an Octadecyl (C_{18}) column. These analytes are baseline resolved from each other in less than 10 min. Additionally, a second LC method using UV absorbance and FL detection was developed to separate psilocybin, psilocin, norpsilocin, norbaeocystin, baeocystin, and aeruginascin.

LC-FL has been used for the determination of psilocybin with derivatization to improve sensitivity.[4] In a forensic laboratory, however, derivatization would be more time-consuming and costly. In the present study, native fluorescence data were obtained using a stop-flow function on the LC instrument to collect fluorescence spectra. An LC-FL method was developed for the six analytes using optimal excitation and emission wavelengths. Fluorescence is a much more sensitive and selective means of detection, which will be critical to the analysis of complex sample matrices such as gummies and chocolates.

B93 Distinguishing Between the Tandem Mass Spectra of Positional Fentanyl Analogs Using the Expert Algorithm for Substance Identification

Alexandra I. Adeoye, MS, West Virginia University, Morgantown, WV; Sandra E. Rodriguez-Cruz, PhD, DEA Special Testing and Research Laboratory, Dulles, VA; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: In this presentation, attendees will learn about the correlations that exist between the ion abundances of replicate tandem mass spectra and how these correlations are used to distinguish between spectrally similar positional fluorofentanyl analogs.

Impact Statement: This presentation will present the forensic community with a robust mass spectral algorithm capable of distinguishing between spectrally similar fluorofentanyl analogs using their tandem mass spectra collected under varying instrumental parameters or on different instruments. The Expert Algorithm for Substance Identification (EASI) will also provide practitioners with an algorithm that minimizes false identifications and improves confidence when reporting their identifications in testimonies, especially in the absence of reference spectra on the same instrument.

Abstract Text: The identification of positional isomers is one of the most significant challenges currently facing the seized drug community. Traditional techniques, such as Gas Chromatography/Electron Ionization/Mass Spectrometry (GC/EI/MS), or emerging techniques such as Tandem Mass Spectrometry (MS/MS) with ambient ionization sources like Electrospray Ionization (ESI) or Direct Analysis in Real Time (DART) are all employed by seized drug analysts to distinguish between isomers. For example, the opioid fluorofentanyl can exist as three positional isomers, which have significantly different potencies, so analysts must differentiate them. Previously, we have demonstrated the application of EASI to the differentiation of isomeric fentanyl analogs, synthetic cathinones, and cannabinoids using GC/EI/MS data. This study expands our work with EASI to DART-MS/MS data.

Our central hypothesis is that the relative ion abundances within replicate tandem mass spectra are not independently variable but exhibit varying levels of correlation with other fragment ions. We use these measured correlations (confirmed by Pearson correlation matrices) between normalized abundances in replicate spectra to build a series of general linear models that model each measured ion abundance. We then assess the fitness of measured and predicted ion abundances for hundreds of known positives and known negatives for each model. Our hypothesis is supported by unimolecular fragmentation theories like Rice–Ramsperger–Kassel–Marcus (RRKM).

For this presentation, more than 100 replicate spectra were collected for each fluorofentanyl isomer at four different collision energies on a triple quadrupole mass spectrometer equipped with a DART source. The replicate spectra were randomly assigned 80% to a training set and 20% to the test/validation set. Because the fragment abundances vary at different collision energies, the 30 most abundant fragments across all collision energies were selected as variables for the linear models. The variables were entered into a stepwise addition method for general linear modeling using SPSS (Version 29.1, IBM). We compared EASI to a consensus spectrum approach, which uses the average spectrum of all replicates of a substance as the exemplar spectrum for the substance, using similarity and dissimilarity metrics. These metrics included the dot-product and the mean absolute residual. Each metric was then used as a binary classifier to generate Receiver Operating Characteristic (ROC) curves and to determine the true and false positive rates over a range of threshold values. The Area Under the Curve (AUC) was then calculated to assess the performance of each metric and its supporting model.

The residuals from the EASI models were generally two times smaller than those from the consensus-based approach. EASI typically reduced the error rate from ~15% for the consensus approach to < 5% for EASI. EASI had greater accuracy, as determined by greater AUCs and smaller error rates at a conservative, arbitrary threshold of 1 false positive. This presentation demonstrates the extension of EASI to tandem mass spectra generated using multiple collision energies with DART-MS/MS instrumentation. Further, it highlights the utility of EASI for compound identification regardless of the instrumental configuration.

B94 The Optimization and Validation of a Method for Rapid Quantitation of Fentanyl in Seized-Drug Samples Using Direct Analysis in Real Time-Mass Spectrometry (DART-MS)

Sandra E. Rodriguez-Cruz, PhD, DEA Special Testing and Research Laboratory, Dulles, VA*

Learning Objectives: After attending this presentation, attendees will learn how the standardized DART-MS qualitative method used throughout Drug Enforcement Administration (DEA) laboratories was optimized and validated for rapid quantitation of fentanyl in seized drug samples.

Impact Statement: This presentation will impact the forensic science community by providing an overview of the steps undertaken to demonstrate the linearity, sensitivity, precision, and accuracy of the rapid quantitation method for fentanyl using DART-MS.

Abstract Text: The rise of illicitly manufactured fentanyl and Fentanyl-Related Substances (FRS) has overwhelmed seized-drug laboratories and resulted in a surge of analysis requests, increasing backlogs and turnaround times. Traditional drug laboratory techniques such as gas chromatography, liquid chromatography, mass spectrometry, and their combinations, are commonly used to analyze these samples and identify low-level components such as fentanyl, FRS, precursors, adulterants, synthetic byproducts, and newly appearing substances. However, some of these methods require careful sample preparation steps and lengthy analyses, further contributing to delays in the issuance of final results. Purity analyses are seldom included within the analytical schemes employed by many drug laboratories and, even though these analyses are not required in many jurisdictions, their omission does leave a gap in the information collected. As forensic drug laboratories continue to be bombarded with submissions of fentanyl and other drugs, the need for developing and incorporating more efficient analyses and techniques to fill these informational gaps increases. DART-MS has proven valuable as an identification tool in laboratories by providing fast and reliable qualitative/screening results.[1-3] However, its application to quantitative analyses in the seized-drug laboratory has been limited.

In this presentation, a rapid method for the quantitation of fentanyl will be presented. The method requires minimal sample preparation and is an optimized version of the standardized 12-second DART-MS method already used throughout DEA laboratories for qualitative analyses. Testing solutions were prepared by diluting the sample material in methanol. These solutions were then deposited onto sampling cards and ionized using a 3-second pulse of metastable helium atoms while protonated molecular ions for fentanyl and isotopically labeled (fentanyl-d5) were monitored over a 12-second MS acquisition window using selected-ion monitoring. Prior to validation, the DART ionization parameters were evaluated to optimize the helium temperature and the length of the ionizing pulse. Peak area ratios of fentanyl to its isotopically labeled counterpart proved to be suitable to monitor various fentanyl levels. Subsequent validation of the method included assessment of its linearity, sensitivity, between-batch precision, between-day precision, and a multi-prong assessment of its accuracy, including investigation of tablet-matrix effects.

Validation studies demonstrated linear behavior ($r > 0.999$) over a fentanyl concentration range of 2 – 250 µg/mL and a calculated Limit Of Quantitation (LOQ) of 3.8 µg/mL. Validation also demonstrated excellent within-batch and between-day precision (RSDs < 6%), along with high accuracy (generally < 10% error). Assessments involved numerous analyses ($n = 57$) of atrol (QC) sample across the validation period and the testing of 9 laboratory-prepared and 15 casework samples that were submitted to the DEA Special Testing and Research Laboratory.

Combining the use of DART ionization and an automated sampling set-up with the sensitivity and quantitative capabilities of a triple quadrupole mass spectrometer, a simple experimental protocol was designed that allows: (1) contemporaneous establishment of a 3-point calibration curve; (2) analysis of negative and positive controls; and (3) analysis of two independent samples (in duplicate), all within a single analysis batch of about 4.5 minutes.

B95 It Could Happen to You: A Forensic Scientist in the Crosshairs—Epilog

Laskowski E. Gregory, MPA, Criminalistics Services International, Bakersfield, CA*

Learning Objectives: Attendees, especially criminalists, will learn that their work will be scrutinized years, even decades, after their work on a case. That scrutiny may result in a lawsuit filed against them for personal monetary damages despite the perception that working for a law enforcement agency may make them immune from these types of lawsuits. Today's courts, especially in the state of California, may be more willing to allow these types of lawsuits to go forward. Filed court complaints proffered to these courts may list things that have no basis in fact. To help guard against these types of lawsuits, attendees will learn what they will need to protect themselves from such lawsuits and what they need to do in terms of their casework, which will include their work notes and their work product, and to be vigilant as to peer, technical, and administrative reviews of their work.

Impact Statement: This presentation will impact the forensic science community in teaching them to be more aware on how they conduct casework in terms of taking notes, photographs, making charts, and, to some extent, listing the reasons for the decisions they made. The main gist of this will be to instill the process of properly documenting the work they perform.

Abstract Text: In August of 1993, Richards Williams was charged with the murder of his wife in a remote location in San Bernardino County, CA. After three criminal trials, and possibly due to the testimony of a forensic odontologist regarding a potential bitemark on the decedent's arm, Mr. Williams was convicted of murdering his wife. Years later, the forensic dentist recanted on a portion of his testimony regarding the bitemark evidence. A trial court in California vacated the conviction and set Defendant Williams free, going so far as to declare him factually innocent.

In 2019, a law firm took up his case of wrongful conviction and ordered a civil trial. Many experts were called. Expertise ranged from crime scene investigation, DNA, analysis, pathology, and digital imaging. The judge in this civil trial ruled in favor of the defendants, stating that he saw nothing to incriminate the officers, detectives, and the criminalist of the San Bernardino Sheriffs Department.

Not satisfied with this ruling, plaintiff's counsel began the process of "judge shopping." They made their case with the 9th Circuit Court of Appeals, branded the most liberal court in the nation. That court found that the trial court had erred; therefore, a trial in the Federal District Court in Los Angeles must be held to re-examine the matter.

In July of 2025, a civil trial was held. The District Court judge severely limited the testimony, literally hamstringing the defense in limiting what experts they could produce and the length of their testimony. The plaintiff had a two-prong attack. First, attack the crime scene detectives, showing them as biased and collaborating to prevent the coroner's investigator from performing a liver temperature test in a timely manner to establish the Postmortem Interval (PMI). Second, make allegations that the criminalist investigating the scene, who later analyzed the evidence, planted fiber evidence on the victim's finger to frame the defendant.

After two weeks of trial, the jury returned their verdict. The criminalist was exonerated of all wrongdoing. The County of San Bernadino was held liable for $24 million dollars for negligent prosecution. The case is under appeal by the defendants.

B96 Criminalistics Gone Wild—Does Technology Kill the Truth?

Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; Anna S. Duggar, PhD*, Loyola University New Orleans, New Orleans, LA; Claude Roux, PhD*, University of Technology Sydney (UTS), Ultimo, New South Wales, Australia; Michelle D. Miranda, PhD*, Center for Criminal Justice Studies, Farmingdale, NY; Sheila Willis, DSc*, Leverhulme Research Centre for Forensic Science, Dublin, Dublin, Ireland; Mark Profili, MFS*, Towson University, Towson, MD*

Learning Objectives: After attending this presentation, attendees will: (1) reflect upon the foundations of knowledge and "truth-seeking" that are central to all forensic science disciplines; (2) consider the ongoing tension between current/emerging technologies and human intervention in forensic science endeavors; and (3) weigh the need for critical thinking to remain at the forefront of the forensic science process in education, research, and practice, regardless of technological and digital transformations.

Impact Statement: This presentation will impact the forensic science community by highlighting the challenges to be overcome in order to gain value from modern technology while still remaining true to science and the scientific foundations of forensic endeavors. The emphasis will be on the need for scientific logic, reasoning, and critical thinking rather than isolated test results, with the broader goal of addressing the perils of excising human cognition from forensic science casework, education, training, and research.

Abstract Text: Even silos are built on solid ground. Despite what that silo houses, it can withstand external forces when it is built on a foundation that supports its structural integrity. While there are myriad disciplines and subdisciplines in forensic science (often relegated to discrete "silos"), the foundation of these disciplines should be built on a set of shared, core principles. As all sciences are interconnected via a scientific method, so all forensic disciplines are interconnected by a shared philosophy and perspective. Technological advances—from portable high-tech instrumentation to advanced databasing to AI reporting—can both distract practitioners from the critical thinking skills that allow for interdisciplinary problem solving, and also impact the scientist's ability to evaluate, interpret and communicate the answers to complex questions that arise during the course of an investigation.

A panel of experienced practitioners and academics will discuss the need to be conscious of the basics in a fast-moving world where seductive technological advances can lure the scientist into ultra specialization—valuing isolation and knowing more about less.

This session will give the audience an opportunity to reflect on the challenge of applying core principles of forensic science in an era marked by phenomenal development of technology and automation. The demand for forensic services has grown exponentially. To service this demand, every effort is made to streamline services, automate processes, and reduce human intervention. This approach is ideal for a clinical environment with laboratory technicians, uniform specimens, and controlled expected findings. It is less appropriate when the principles of forensic science, as outlined in the Sydney Declaration, need to be considered in order to provide a reliable opinion by forensic scientists. Such innovation, coupled with the burgeoning shift toward AI, requires us to pause and consider where technology may end, and the human may begin.

This interactive panel discussion will view these issues through the conference theme of "Back to Basics," reflecting on the way in which our fundamental identity as forensic scientists interacts with the ever-evolving technological landscape of our forensic capabilities.

B97 Standards Development Activities in Trace Materials

Sandra Koch, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Celeste M. Grover, MSFS, Oregon State Police, Forensic Services Division, Clackamas, OR; Jennifer L. Remy, MS, North Carolina State Crime Laboratory, Raleigh, NC*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the examination and interpretation of trace materials.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness of standards development activities related to trace materials analysis and interpretation. It will also increase awareness regarding training, tools, and resources that support implementation of standards, the American Society for Testing and Materials (ASTM) process, and how the Organization of Scientific Area Committees (OSAC) and ASTM standards development process plans to work more together.

Abstract Text: The OSAC for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to the Standards Development Organizations (DSOs) that ballot and publish them. The OSAC also reviews published standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus based, technically sound standards.

As of August 1, 2025, the Trace materials Subcommittee has 23 published and 8 proposed standards on the OSAC Registry. Additional documents are making their way through the subcommittee, OSAC Registry, and ANSI/ASTM processes.

During this presentation, Trace Materials standards development activities relating to fibers, geology, glass, hair, interpretation, physical fit, polymers, terminology, and trace recovery will be discussed. These include:

1. OSAC proposed standards on the Registry:
   - OSAC 2023-N-0005 Standard Practice for Training a Forensic Glass Practitioner
   - OSAC 2023-N-0011 Standard Practice for a Physical Fit Analysis Training Program
   - OSAC 2022-N-0018 Standard Practice for a Forensic Fiber Training Program
   - OSAC 2023-N-0027 Standard Guide for Forensic Trace Evidence Recovery
   - OSAC 2025-N-0017 Standard Terminology Relating to Trace Materials Analysis (added April 1, 2025)
   - OSAC 2024-S-0012 Standard Practice for the Forensic Analysis of Geological Materials by Scanning Electron Microscopy and Energy Dispersive X-Ray Spectrometry (added January 13, 2025)
   - OSAC 2022-S-0017 Standard Guide for Microspectrophotometry in Forensic Fiber Analysis
   - OSAC 2022-S-0019 Standard Guide for Forensic Examination of Fibers

2. Recently published ASTM standards that are going through the Registry approval process:
   - ANSI/ASTM E2926-25 Standard Test Method for Forensic Comparison of Glass Using Micro X-ray Fluorescence Spectrometry
   - ANSI/ASTM E3406-25 Standard Guide for Microspectrophotometry in Forensic Fiber Analysis
   - ANSI/ASTM E3462-25 Standard Guide for Interpretation and Reporting in Forensic Comparisons of Trace Materials

3. Documents currently in development at OSAC or by the SDO:
   - OSAC 2024-S-0015 Standard Guide for Assessing Physical Characteristics and Using Light Microscopy in Forensic Tape Examinations
   - OSAC 2025-S-0011 Standard Practice for Polarized Light Microscopy in the Forensic Examination and Comparison of Soils
   - Standard Guide for Forensic Examination of Textile Damage
   - Standard Guide for Forensic Examination of Fibers and Textiles Using Fluorescence
   - Standard Guide to Raman Spectroscopy in Forensic Polymer Examinations
   - Standard Guide for Using X-ray Diffraction in Forensic Polymer Examinations

4. 5-year revisions being worked on:
   - ANSI/ASTM E3233-20 Standard Practice for Forensic Tape Analysis Training Program
   - ANSI/ASTM E3234-20 Standard Practice for Forensic Paint Analysis Training Program
   - ANSI/ASTM E1967-19 Standard Test Method for the Automated Determination of Refractive Index of Glass Samples Using the Oil Immersion Method and a Phase Contrast Microscope

B98 The Basics of Light Microscopy: Getting the Most Out of Your Microscope

James Neal Schrode, BS, Leeds Precision Instruments, Inc., Minneapolis, MN*

Learning Objectives: After attending this presentation, attendees will understand the fundamental principles of the following aspects of light microscopy: (1) numerical aperture and resolution, (2) magnification, (3) depth of field, and (4) contrast. This will include reviewing how different optical components in microscopes can affect the overall image and image quality for the observer.

Impact Statement: This presentation will impact the performance of examiners using microscopes by providing a better understanding the principles of microscopy, allowing for a more effective use of microscopes in laboratory imaging.

Abstract Text: Microscopes are more than just putting a sample on the stage and looking in the eyepiece. This discussion will review the basics of microscope usage for light microscopy to demonstrate how to more effectively use the microscope in addition to reviewing aspects of microscopy that may be asked about in a courtroom setting.

This presentation will review:

- Different light sources used in imaging and how they affect the color of the viewed sample image
- What is resolution and how is it affected in microscope usage
- The difference between primary and secondary magnification
- How magnification is represented in digital imaging
- Depth of field vs. field of view and what affects both of these
- Contrast
- Comparison microscopes and how two separate optical paths are managed in viewing samples
- Diopter settings and how they affect parfocality and ergonomics

By providing a detailed understanding of microscopy fundamentals, attendees will be able to:

- Better utilize microscopes for their examination process
- Have greater versatility in imaging difficult samples by using aperture diaphragms more effectively
- Fully utilize ergonomic and performance features to make their use of the microscope easier and more comfortable
- Be able to provide more accurate, detailed responses to inquiries about the instruments they use in the workplace for reporting and courtroom testimony

B99 Assessing the Utility of Elemental Profiling to Differentiate the Silt-Sized Fraction of Soils Collected at Varying Spatial Scales

Jack Hietpas, PhD, John Jay College, New York, NY; Peixuan Du, BS, John Jay College of Criminal Justice, New York, NY; Libby A. Stern, PhD, FBI Laboratory, Quantico, VA; Kelly A. Meiklejohn, PhD, North Carolina State University, Raleigh, NC*

Learning Objectives: This presentation will focus on assessing the discrimination potential of the elemental profiles of soils collected from North Carolina. The attendees will learn how to process, collect, and interpret soil elemental profiles using Energy-Dispersive X-Ray Fluorescence (EDXRF).

Impact Statement: This presentation introduces a method for sample preparation and elemental profiling of a size fraction not often utilized in the forensic analysis of soils. By integrating this technique into casework, analysts may improve the usability, reliability, and discriminatory power of soil evidence. The method is accessible to practitioners without extensive geological expertise, potentially broadening its practical application in forensic investigations.

Abstract Text: As a common form of trace evidence, soil can provide useful forensic information to associate people, objects, and locations.[1,2] Its heterogeneous and spatial variable nature—including variations in mineral composition, texture, and biological components —can support or refute case-specific hypotheses.[2] EDXRF offers a rapid, non-destructive method for qualitative and quantitative elemental analysis, providing additional or complementary forensic value to other standard techniques such as color, Polarized Light Microscopy (PLM), and X-ray diffraction.[3] While traditional bulk XRF analysis has been effective in environmental and archaeological applications, its use in forensic casework has been limited by the tendency to homogenize samples, thus losing valuable information gleaned from particle-based approaches. This practice can destroy important information related to mineralogy, particle size distribution, and layered context.[4,5] Also, forensic samples may be too small to be representative of elemental composition given the heterogeneity of soil.

This study analyzed the fine silt and finer fraction (< 63 µm) of 180 previously collected soil samples from three regions in North Carolina. While earlier analyses focused on other forensic methodologies, this research specifically examined the elemental profiles of the fine silt and clay-sized component for its potential to discriminate. This size range is often not analyzed, as it can be difficult to characterize the minerals using PLM (pollen and diatoms are present in this fraction, but require specialized knowledge for their analysis). However, it may provide valuable supplemental information for sample discrimination.[2] The study aims to expand the evidentiary value of soil by using a method that is accessible to practitioners without extensive geological expertise, while preserving the ability to analyze the samples using traditional methods. Soil samples were processed using a modified version of the method outlined by Palenik.[2] EDXRF analysis was performed using a Shimadzu EDX-7200 spectrometer with a 10 mm spot size. Elemental profiling offers a practical and non-destructive method for potentially enhancing the evidentiary value of soil in forensic investigations. The data were compared using a combination of subjective (visual) and quantitative (statistical) methods. The results from this study will help inform the caseworker about the utility of incorporating bulk elemental analysis of the silt-size fraction of soils for sample discrimination.

B100 An Investigation of the Effects of Detonation on the Analysis and Comparison of Electrical Tape Backings

Swathi Murali, Sam Houston State University, Huntsville, TX; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will understand the effects of detonation on the analysis and comparison of electrical tapes using the prescribed analytical scheme for the forensic examination of tapes.

Impact Statement: This presentation will impact the forensic science community, particularly trace evidence examiners, by providing vital information to practitioners on the challenges associated with the comparison of unknown-origin post-blast tape specimens with a known pristine sample.

Abstract Text: Electrical tapes are often examined in forensic laboratories in relation to their use in the fabrication of Improvised Explosive Devices (IEDs). The forensic examination of tapes begins with a macroscopical examination of their physical properties such as color, sheen, dimensions, and/or condition. Subsequently, a physical fit is attempted, which, if successful, provides the strongest association between the recovered specimen and a suspected source. In the case of electrical tapes, such examination is precluded when post-blast specimens are encountered. Consequently, examiners rely on analytical techniques, including Fourier Transform Infrared Spectroscopy (FTIR), Energy-Dispersive Spectroscopy (EDS), and Gas Chromatography/Mass Spectrometry (GC/MS), to study the chemical composition of tapes. Prior research on the forensic examination of tapes has focused on the discriminating capabilities of analytical techniques to differentiate between tapes, primarily using pristine samples. As electrical tapes are evaluated in the context of IEDs, a systematic investigation into the effects of detonation on the analysis of tapes is essential.

The goal of this project was to investigate the effects of detonation on the analysis and comparison of tapes. Thirty black vinyl electrical tapes were subjected to two sets of controlled detonations in collaboration with the Montgomery County Fire Marshall's Office. A subsample of each tape was adhered to the interior of a toolbox and detonated using a TNT explosive charge and a PETN detonation cord. Fifteen specimens were recovered after the first detonation, and 22 specimens were recovered after the second detonation. The pristine and post-blast tapes were characterized using FTIR spectroscopy, EDS, and GC/MS. Subsequently, the analytical information acquired from pristine and post-blast tapes was compared. With FTIR spectroscopy, the presence of additional bands and changes in their shape was observed in the spectra of post-blast tapes. The most common spectral alterations included the appearance of a minor band at ~1100 cm-1 characteristic of TNT and a decrease in the resolution of a shoulder at ~1270 cm-1 associated with the plasticizer. EDS analysis revealed the presence of additional elements, which obscured the detection of certain elements in the post-blast tapes. However, these alterations were not systematic and could be attributed to microheterogeneity due to contaminants or impurities introduced during the detonation. Additionally, the surface of some tapes exhibited thermal damage, which in turn may have affected the penetration depth of the electron beam and subsequent data acquisition. Finally, using GC/MS, the overall chemical composition of tapes was preserved between pristine and post-blast specimens. Acrylate and phthalate were detected in some post-blast specimens, which could be attributed to substrate effects from the toolbox used during the detonation. TNT was also detected in some samples. Overall, FTIR and EDS were sensitive to the effects of detonation, thereby reducing the reliability of these techniques in the comparison of pristine and post-blast tapes. Conversely, GC/MS was found to be more robust to the effects of detonation due to its chromatographic separation of the analytes of interest, thereby preserving the chemical information used for comparison.

B101 The Effects of Adhesives on the Subsequent Fourier Transform Infrared (FTIR) Analysis of Paint and Fibers

Ashlyn Bartley, MSFS, University of New Haven, Tampa, FL; Ted R. Schwartz, MS, University of New Haven, West Haven, CT*

Learning Objectives: Attendees will learn about the impact different types of adhesives have on the trace evidence they come into contact with. Results will include how these impacts differ among the type of adhesive, the type of trace evidence, and the length of contact. Finally, attendees will learn if these impacts affect the FTIR analysis of the evidence and, if so, whether typical sample preparation procedures minimize these effects.

Impact Statement: This presentation can impact the community by bringing light back to the basics of evidence collection at crime scenes as well as the storage and manipulation of traces during laboratory analysis.

Abstract Text: Forensic analysts at both crime scenes and in a laboratory setting are reliant on a variety of adhesives to collect and store trace evidence. The adhesives come into direct contact with evidence such as fibers and paint. This contact introduces a possible risk of contamination from the adhesive onto the evidence. In addition, there is the chance of physical alteration of the evidence upon removal from the adhesive. It was recommended by the Scientific Working Group for Materials Analysis (SWGMAT) in 1999 that adhesives should not be used to collect paint evidence, although there was no such recommendation for other forms of trace evidence.[1] The goal of this project was to investigate if adhesives have a chemical or physical impact on the trace evidence, and whether these differences can be observed during laboratory examination.

In this study, six different types of adhesive materials were utilized to test for their potential chemical or physical impacts on trace evidence. The adhesive materials used in this study were forensic fingerprint lifting tape, gelatin lifters, fingerprint hinge lifters, lint rollers, sticky notes, and packing tape. To simulate common trace evidence, three diverse types of fiber evidence, as well as three different types of paint evidence were collected. The fibers included nylon, polyester, and acrylic; the paints consisted of an automotive clear coat, an exterior house paint, and an interior house paint. All adhesive and evidence combinations were stored at four different storage intervals: 1 week, 4 weeks, 14 weeks, and 24 weeks. Chemical and physical changes were documented by FTIR using an Attenuated Total Reflectance (ATR) objective.

The results showed that there can indeed be a transfer of adhesive to the trace evidence, and the likelihood and amount of adhesive transferred is dependent on the strength of the adhesive used. Fingerprint lifting tape and hinge lifters appeared to have the strongest adhesive. This led to a greater chance of adhesive transfer to the samples and a greater chance of breakage upon removal. Packing tape and lint rollers showed less chance of adhesive transfer and breakage upon removal, while gelatin lifters and sticky notes showed the least amount. There were no differences observed based on the length of time the adhesive was in contact with the samples.

The study revealed that even if adhesive transfers to the sample, there are typically clean, non-contaminated areas on the material to obtain a clean FTIR spectrum. Further studies showed that, during typical sample preparation procedures, the adhesive can be successfully removed prior to instrumental analysis, again leading to clean FTIR spectra.

B102 Using Raman Microscopy to Distinguish Dyed Textile Fibers

Alexis N. Wilcox, MS, ORISE, Quantico, VA; Lydia R. Burnett, MASc, ORISE, Woodbridge, VA; Joseph Donfack, PhD, FBI Laboratory, Quantico, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the discrimination power of Raman microscopy to distinguish between similarly colored textile fibers using various machine learning techniques.

Impact Statement: This presentation will impact the forensic science community by helping to determine whether or not Raman microscopy may be a useful future supplemental technique to distinguish dyed textile fibers.

Abstract Text: Previous studies have shown success at distinguishing dyed fibers using Raman microscopy. However, these studies analyzed fibers without mounting media and with obvious differences in fabric types, dye colors, and dye classes. This study aims to distinguish between similarly colored textile fibers following the fiber sample preparation protocol implemented for casework analysis at the Federal Bureau of Investigation (FBI) Laboratory Trace Evidence Unit.

To achieve this goal, fibers comprising 144 dyed fabrics from the same dye manufacturer were mounted on glass slides with permount and glass coverslips. These dyed fabrics can be broken into six sub-groups based on the dye color and dye class: Direct Blue (22), Disperse Blue (37), Reactive Blue (36), Direct Black (11), Disperse Black (18), and Reactive Black (20). Three fibers were analyzed per dyed fabric using a Thermo Fisher DRX3 Raman Microscope with a 785 nm laser, 10mW power and 50x objective. The exposure time and number of exposures varied for each spectrum to maximize Raman peak clarity and intensity.

All spectra were baseline subtracted and any uninformative spectra were removed from the sample set. Various Machine Learning (ML) techniques were used to investigate the discrimination power of Raman Microscopy for dyed fibers, including: Principle Component Analysis (PCA), K-Nearest Neighbors (KNN), Support Vector Machine (SVM), and Random Forest (RF). For each chemometric, 6 models were trained using different spectral ranges (full vs fingerprint) and prediction data (class, color, and class-color) using a 10-fold cross validation. The accuracy, precision, recall, and f1-score were calculated for each model.

Out of the four ML techniques, the PCA and SVM performed similarly. The RF performed the third best, followed by KNN. Out of the six different prediction models, the class model using the fingerprint region consistently performed the best. For this model, PCA, SVM, and RF scored above 0.92 across all metrics. The KNN still performed well with the lowest score being the recall at 0.86 a.u. for the fingerprint region class model. The full range class model also performed well with the lowest score being recall at 0.85. The recall was generally the lowest score out of the four performance metrics because the models were prioritizing the correctness of the model and minimizing false positives, which is beneficial to forensic analysis. Overall, this study shows the potential of Raman Microscopy to distinguish between the dye class and color of fibers and potentially predict the dye class and color depending on the ML technique used. More validation studies are still needed before Raman microscopy should be used to analyze dyed fibers in forensic casework. These studies should incorporate more laser wavelengths, a variety of fabric types and similar dye colors.

B103 A Deep Transfer Learning Framework for the Detection of Ignitable Liquid Residues in Burned Substrates Across Inter-Laboratory GC/MS Systems

Ting-Yu Huang, PhD, Central Police University, Taiwan, Guishan Dist., Taoyuan, Taiwan; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: Following this presentation, attendees will gain an understanding of the methodology behind developing Artificial Intelligence (AI) - based image classification algorithms and their performance in analyzing Gas Chromatography/Mass Spectrometry (GC/MS) signals from Ignitable Liquids (ILs) and fire debris samples. The discussion will also include the technical challenges of this innovative approach, aimed at enhancing its effectiveness and assisting forensic analysts in improving their efficiency in evidence analysis.

Impact Statement: The impact of this study is to demonstrate how summed ion spectra, when combined with AI-powered image classification algorithms, can enhance data consistency across various GC/MS systems despite differences in retention times. The intelligent framework offers potential for interlaboratory use such as maintaining reproducibility and accuracy of analytical methods and data analysis across different forensic laboratories.

Abstract Text: Examining fire debris for the presence of ILs provides strong evidence of arson during investigations. The standard test method utilizing GC/MS is widely employed by forensic laboratories for analyzing fire debris.[1] However, interpreting GC/MS data relies on analysts comparing chemical profiles visually with reference samples. Additionally, GC/MS data can encounter retention time alignment issues across different analytical runs due to operational variations, which complicates interlaboratory consistency.[2] Summed Ion Spectra (SIS) are created by combining ion intensities at each mass-to-charge (*m/z*) ratio across all scans within total ion chromatograms. The SIS provides an alternative method of data representation, highlighting the chemical compositions of a sample, and has proven useful in various chemometric analyses of fire debris.[2] Convolutional Neural Networks (CNNs) are powerful AI models for analyzing visual data by automatically extracting hierarchical features through layered structures.[3] This enables CNNs to perform accurate image classification tasks. This study aimed to develop an AI-powered system using SIS classification with a deep CNN to detect IL residues in burned matrices. The research objectives were to assess whether the AI system could detect ILs automatically and whether it could analyze data collected from various GC/MS systems without the issue of retention time shifting.

To test the hypotheses, four brands of 87-grade gasoline from local gas stations in Huntsville, TX, along with Nylon carpet, were selected as the IL and matrix, respectively. A total of 585 samples, including diluted gasoline, burned carpets, and simulated fire debris samples, were analyzed using Headspace Solid-Phase Microextraction combined with GC/MS (HS/SPME-GC/MS) to produce an intra-laboratory dataset. The inter-laboratory dataset was created from GC/MS data of neat gasoline, burned substrate, and fire debris samples collected by the National Center for Forensic Science.[4-6] All GC/MS data were converted into SIS format by selecting specific *m/z* and retention time regions characteristic of gasoline chemical profiles. A pre-trained CNN was adapted to classify the SIS into two categories: presence or absence of gasoline.[7]

The experimental results showed that the CNN achieved a validation accuracy of 98.72% after retraining. When tested with internal lab-made samples, the CNN achieved 95.86%±0.59% accuracy in detecting simulated fire debris samples with concentrations above 25 µg/20-mL headspace vial. For inter-laboratory samples, which were more challenging, the CNN achieved 96.87±0.58% accuracy in detecting neat gasoline samples, even when they were weathered or degraded to varying extents. Additionally, the CNN achieved 100±0% accuracy in detecting fire debris samples with high IL contribution in the chromatograms, despite being weathered to high levels and spiked on matrices different from those in the training dataset.

In conclusion, the proposed AI-powered model was effectively created with the ability to generalize features, eliminating the need for retention time alignment across different laboratories and the necessity for extensive retraining. The workflow for constructing AI models can be readily adapted to real crime scenes, which often have few samples and are straightforward to model. This AI-based method demonstrates potential for forensic fire debris analysis.

B104 A Refinement of the Expert Algorithm for Substance Identification (EASI) to Predict ASTM E1618-19 Ignitable Liquid Classes From Gas Chromatography/Mass Spectrometry Data of Ignitable Liquid Residues

Hannah McMillen, MS, West Virginia University, Morgantown, WV; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: After attending this presentation, attendees will understand how EASI compares to common machine-learning methods for the classification of ignitable liquids into their American Society for Testing and Materials (ASTM) E1618-19 classes when challenged with the same training and test sets.

Impact Statement: This presentation will impact the forensic science community by providing a refined EASI model that will help analysts make more informed decisions about the presence of ignitable liquids in fire debris casework samples. By comparing EASI to common machine learning models, the presentation will provide analysts with a comprehensive view of the benefits and drawbacks to each modeling method.

Abstract Text: Although standard methods like ASTM E1618-19 help analysts identify ignitable liquid residues into arbitrary classes based on chemical composition, ASTM E1618 does not provide any quantitative measures uncertainty or error rate, as required by *Daubert* or Federal Rules of Evidence 702.[1] To provide a more objective means to interpret fire debris evidence, we examined the ability of the Expert Algorithm for Substance Identification (EASI) to identify ignitable liquid classes from the Total Ion Spectra (TIS) of Gas Chromatography/Mass Spectrometry (GC/MS) data files.[2,3] TISs have been promoted by others to help remove variability caused by the GC dimension.[4] This work focuses on refining the model for the identification of gasoline samples from other ignitable liquid classes and background pyrolysis, and comparing it to commonly researched machine learning models, like Linear Discriminant Analysis (LDA), Quadratic Discriminant Analysis (QDA), and Mahalanobis distance.[5-7].

The training set consists of 53 gasoline samples from the National Center for Forensic Science (NCFS) database weathered from 0-75%.[8] The TISs were then preprocessed using two different methods of ion selection and normalization. EASI uses mixed stepwise selection to build multivariate general linear models of each of the most abundant ions in the mean TIS spectrum of the training set. Each dependent ion is sequentially modeled using the remaining ions as covariates.

Currently, accuracies of the 15 most abundant ion predictions per gasoline sample using EASI were evaluated using both Pearson product moment correlations and the Mean of Absolute Residual (MAR) for the training and test sets, which contained a total of 241 gasoline samples, 977 non-gasoline liquid samples, and 1,735 substrate/background samples. These measures were then used for binary classification (i.e., gasoline present or not present) and assessed using Receiver Operating Characteristic (ROC) curves and confusion matrices. The greatest Area Under a ROC curve (AUROC) of 0.993 was observed for MAR using the ions selected according to their rank abundance and normalized such that the sum of ion abundance is one. Classification using MAR provided a false positive rate of less than 3% at a true positive rate of 99.5%. The model had no errors from background samples, and most of the 3% false positives for the gasoline model were caused by samples from the aromatic class, which is understandable given the chemical similarity between the classes.

We also assess the two most significant factors in the EASI algorithm: (1) the number of ions modeled in the TIS, and (2) weighting the models or residuals to enhance the discrimination of closely related classes like gasoline and aromatics. The use of more ions in the model decreased the error rate to less than 1%, and weighting the variables provided almost errorless classifications among the ~3,000 samples.

Comparing EASI, and all its refinements, to LDA, QDA, and Mahalanobis distance provides a comprehensive understanding of EASI's effectiveness and applicability to fire debris and ignitable liquid residue data.

B105 An Evaluation of Kinetic and Thermodynamic Approaches to Predict Evaporation of Gasoline

Jenna E. Leppek, BS, Michigan State University, Canton, MI; Hannah Jewell LaVoie, BS, Michigan State University, Okemos, MI; Victoria L. McGuffin, PhD, Michigan State University, East Lansing, MI; Ruth Waddell Smith, PhD, Michigan State University, East Lansing, MI*

Learning Objectives: After attending this presentation, attendees will gain an understanding of both a kinetic and thermodynamic approach to predict evaporation of gasoline for fire debris applications.

Impact Statement: This work will demonstrate application of the kinetic and thermodynamic models to predict chromatograms corresponding to gasoline evaporated to different levels. The predicted chromatograms, which can be generated in a time- and cost-efficient manner, can form the basis of an extensive reference collection to identify evaporated liquids in fire debris samples.

Abstract Text: Identification of ignitable liquids in fire debris samples often involves comparison of the chromatogram of the debris to that of evaporated reference liquids. However, experimental evaporations of reference liquids can be time consuming and resource intensive. Research in our laboratory is focused on modeling the evaporation process using kinetic and thermodynamic approaches.[1] In the kinetic approach, evaporation rate constants are predicted as a function of retention index, whereas in the thermodynamic approach, vapor pressures are predicted as a function of retention index.[1-5] In each approach, predictions are based on retention indices such that the identity of compounds in the liquid need not be known.

Initial fixed-temperature kinetic and thermodynamic models were developed based on evaporation rate constants and vapor pressures, respectively, of *n*-alkanes at 20 °C.[1] The models were subsequently used to predict chromatograms of gasoline evaporated to different levels at room temperature. Model performance was evaluated based on correlation between predicted and experimental chromatograms. Both fixed-temperature models performed similarly with strong correlation between predicted and experimental chromatograms at evaporation levels ranging from 30%–90%.[1]

The next step in this work is to develop variable-temperature kinetic and thermodynamic models and to evaluate the performance of each approach in predicting evaporation. For kinetic model development, evaporation rate constants of *n*-alkanes at 5, 10, 20, 30, and 35°C were determined experimentally. For each temperature, the natural logarithm was plotted as a function of retention index to generate the corresponding fixed-temperature model. Using the same data (rate constants at all five temperatures), multiple linear regression was performed to generate the variable-temperature kinetic model. Fixed- and variable-temperature thermodynamic models were developed in a similar manner, albeit using standard vapor pressures for the *n*-alkanes calculated based on Antoine coefficients available in the literature.[6,7]

To evaluate model performance, gasoline samples were experimentally evaporated in an aluminum heating block, which was fabricated in-house to allow evaporation under controlled temperature conditions. Evaporated samples were analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) and the experimental chromatograms were compared to those predicted using the fixed- and variable-temperature kinetic and thermodynamic models. As an example, for gasoline evaporated to 40% at 30°C, strong correlation was observed between predicted and experimental chromatograms for both the fixed-temperature kinetic model ($r = 0.9872$) and thermodynamic model ($r = 0.9886$). The variable-temperature models also demonstrated strong correlation between predicted and experimental chromatograms, $r > 0.98$, for both approaches. In this presentation, the basis of the kinetic and the thermodynamic modeling approaches will be discussed in more detail, along with a more detailed evaluation of their performance in predicting evaporation of gasoline.

B106 The Application of a Conditional Source Estimation Method Using Competitive Similarity to Aluminum Powder Sources From Detonated Improvised Explosives Device

Janean Hanka, MS, South Dakota State University, Brookings, SD; Jack Hietpas, PhD, John Jay College, New York, NY; Danica M. Ommen, PhD, Iowa State University, Ames, IA; JoAnn Buscaglia, PhD, FBI Laboratory, Quantico, VA; Christopher P. Saunders, PhD, South Dakota State University, Brookings, SD; Donald T. Gantz, PhD, George Mason University, Fairfax, VA*

Learning Objectives: Attendees of this presentation will gain an understanding of the classes of algorithms that support conditional inference of source, leading to a working understanding of the foundational and predictive validity of a suggested source of the recovered trace objects presented by an automatic identification system.

Impact Statement: This presentation will provide forensic scientists with an understanding of the developed method and algorithm so they will be able to use them appropriately in casework.

Abstract Text: In forensic science, it is desirable to have an automated identification system assist the examiner by suggesting the potential source of a recovered object. However, the features and structure of a recovered object may be of a fundamentally different nature than the control objects that were used to build the automated identification system. The two most common examples of this phenomenon are the comparison of a latent print with a fully rolled/inked fingerprint, and the comparison of a questioned document to a "London Letter," or other document from an individual that was written under controlled-collection conditions. To address this, a conditional source estimation method (using competitive similarity) was developed for handwriting and was later extended to fingerprints.[1-3]

Our current focus is on Improvised Explosive Devices (IEDs) and recovered aluminum (Al) powders from said devices. We have presented results at prior AAFS meetings on the utility of micromorphometric (size and shape) particle data for the discrimination of sources of Al powders in IEDs. The Al powders data set is composed of 100s to 10,000s of particles per source for which micromorphometric measurements were taken on each particle; however, these data only contained Al particles from undetonated materials. In post-detonation cases, there will be a loss of particles as the Al powder is burned; we will assume that the smaller particles will be harder to recover and the chance that the blast consumes the Al particles is inversely proportional to the size of the particles. Given these assumptions, we extend the handwriting/fingerprint conditional source estimation method to the micromorphometric data from Al powders, conditioned on the size of the particles.

To do this, we could take a naive approach to building up a classifier, which is to simply subset the particles by their different size categories and then build a classifier within each size category. The problem with this approach is that certain collections of particles in unexploded samples will have radically differing base rates for the size measurements than the rates of the size measurements of particles in post-detonation samples. This suggests that a classifier that is orthogonal, in some sense, to the information about source of particles contained in the distribution of the sizes of particles is needed. This problem is analogous to that which occurs in handwriting identification, where the handwriting identification needs to be orthogonal to the authorship identification. The competitive similarity learning algorithm provides a classifier that is orthogonal to the size of the particles recovered.

Although the main focus of this presentation is on the statistical design and validation of learning algorithms to address this task, for forensic scientists to be able use the output of these algorithms, it is necessary to have a working understanding of the foundational and predictive validity of the resulting suggested source of the recovered trace objects.

B107 Evaluating Reporting Practices in Fingerprint Comparisons Using Information Theory: Five Response Categories Are Better Than Three

Thomas Busey, PhD, Indiana University Bloomington, Bloomington, IN; Jeffrey Starns, PhD, UMass Amherst, Amherst, MA; Meredith Coon, MFS, Aver, LLC, Columbia, MD; Nada Aggadi, BA, Indiana University, Bloomington, IN; Andrew Cohen, PhD, Umass Amherst, Amherst, MA*

Learning Objectives: The presentation will describe a novel approach to characterizing human performance in forensic settings, which uses all of the available information across a set of judgments about a pair of impressions. We use concepts such as Information Theory to describe the information gained by a forensic science consumer (e.g., investigators, judges, attorneys) about the critical question of interest—are two fingerprint impressions from the same source?

Impact Statement: Forensic examiners in various disciplines use scales of different sizes to communicate their determinations. We demonstrate that for friction ridge comparisons (and similar disciplines), an expanded five-conclusion scale is superior to the traditional three-point Exclusion/Inconclusive/Identification scale and is clearly superior to an ID/No-ID scale. Laboratories that currently use a three-conclusion scale should evaluate the increased utility of an expanded scale.

Abstract Text: Forensic fingerprint examiners communicate the results of their comparisons using a categorical decision scale that traditionally has only two or three categories. Newer scales with five categories have been proposed and, in some cases, adopted. In the present work, we model existing fingerprint comparison data using an approach that characterizes the amount of information provided by examiner decisions when they use a given scale. We use a technique called Expected Information Gain (EIG), which is a measure of the amount of information that will typically be gained about the relation between latent and comparison prints. A high EIG value means an examiner's response is likely to provide substantial information regarding whether the two impressions originated from the same source. EIG considers all of the available information, including that provided by Inconclusive conclusions.

We demonstrate that the five-response-category scale produces an overall higher information gain, maintains high information gain even for risk-averse examiners, is more tolerant of non-optimal decision thresholds, and tends to encourage examiner decision thresholds that are very close to optimal, especially the critical decision threshold that determines an identification response. We further show that all of these advantages of the five-response-category scale are robust against variations in the base rates of a mated pair. In addition, there appear to be relatively few negative aspects of this scale, and larger scales are unlikely to produce marked improvements over five categories.

The current work is an endorsement of efforts to shift to five-response-category decision scales in the friction ridge discipline.

B108 Forensic Fingerprint Detection Through Adhesive Tapes Using Optical Coherence Tomography

Jiayun Liu, PhD, Home Team Science and Technology Agency, Singapore, Eddie Tan, Home Team Science and Technology Agency, Singapore; Yan Wen Crystal Tan, BSc, Home Team Science and Technology Agency, Singapore;Chin Chin Lim, Home Team Science and Technology Agency, Singapore;Chiew Yung Yang, MFSA, Home Team Science and Technology Agency, Singapore*

Learning Objectives: By attending this presentation, participants will:

- Understand the principles and capabilities of Optical Coherence Tomography (OCT) as a non-destructive imaging technique for visualizing latent fingerprints beneath adhesive tapes, enabling them to evaluate its potential integration into their forensic workflow.
- Learn about the effectiveness and limitations of OCT imaging across different types of adhesive tapes, multiple layer configurations, and various substrate materials, allowing them to assess the technique's applicability to their specific forensic cases.
- Gain practical knowledge about the relationship between tape optical properties and fingerprint visualization success, helping them make informed decisions about when and how to apply this technique in their forensic examinations.
- Recognize how this non-destructive imaging approach can be implemented early in the forensic examination process while preserving evidence integrity for subsequent analyses, enabling them to optimize their evidence processing sequence.

Impact Statement: This presentation introduces a novel, non-destructive approach to fingerprint detection that addresses a significant challenge in forensic science: the examination of adhesive tapes without compromising evidence integrity. The technique's ability to visualize latent fingerprints through multiple layers of tape without physical or chemical treatment represents a substantial advancement in forensic methodology. This innovation could significantly reduce evidence processing time, particularly beneficial in time-sensitive cases, while preserving the evidence for subsequent analyses such as DNA testing or trace evidence examination. By providing forensic laboratories with a rapid screening tool that can be implemented early in the examination process, this method has the potential to enhance the efficiency of forensic workflows and increase the success rate of fingerprint recovery from adhesive tapes. Furthermore, the quantitative analysis of different tape materials' optical properties offers valuable insights for future development of forensic imaging techniques, contributing to the field's ongoing technological advancement.

Abstract Text: Adhesive tapes frequently serve as crucial evidence in forensic investigations, often bearing latent fingerprints that can link suspects to criminal activities. Current methods for fingerprint recovery from tapes typically involve physical or chemical treatment, which can potentially damage prints and compromise evidence integrity. This research focuses on OCT as a non-destructive imaging technique for visualizing latent fingerprints beneath adhesive tapes, offering a solution that preserves evidence for subsequent analyses.

We systematically evaluated the technique's effectiveness across different types of tapes, multiple layer configurations, and various substrate materials. The study revealed that fingerprint visualization capability varies significantly with optical properties of tapes. Transparent and packaging tapes demonstrated excellent results, allowing fingerprint visualization through multiple layers, while colored insulating tapes showed limited penetration depth due to higher optical absorption. These observations were quantitatively supported by visible Near Infrared (vis-NIR) transmittance measurements for adhesive tapes at the operating wavelength.

Substrate dependency studies across various materials demonstrated the technique's versatility, with consistent performance on glass and plastic substrates, while paper substrates showed some degradation in image quality due to their fibrous structure. The system achieved rapid scanning capabilities, requiring less than one minute to scan a 10 mm × 10 mm area. The fingerprint can be imaged at a resolution of over 3,000 dpi.

In addition, an algorithm was developed to reconstruct fingerprints from the three-dimensional OCT topography. Since latent prints deposited on curved or irregular surfaces do not align with a single imaging plane, the algorithm extracts different portion of the fingerprint across multiple depths to generate the fingerprint in its entirety. This allows OCT to extend beyond simple surface visualization, enabling reliable recovery of fingerprints from non-planar or layered objects.

This research demonstrates OCT's potential as a valuable forensic tool, particularly for preliminary evidence screening. The technique's non-destructive nature and rapid imaging capability make it especially suitable for implementation early in the forensic examination process. While current limitations exist, particularly with colored tapes, spectral measurements suggest that system optimization could extend the technique's applicability to a broader range of tape materials.

B109 Standards Development Activities Related to Friction Ridge Examination

Steven C. Johnson, BS, Ideal Innovations, Inc., Arlington, VA; Heidi Eldridge, PhD, The George Washington University, Washington, DC*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards related to the examination of friction ridge detail from the hands and feet.

Impact Statement: The presentation will articulate the impact on the forensic science community by creating greater awareness of standards development activities pertinent to the examination of friction ridge detail.

Abstract Text: The Organization of Scientific Area Committees for Forensic Science (OSAC) was created in 2014 through a cooperative agreement between the National Institute of Standards and Technology (NIST) and the Department of Justice (DOJ) to address the lack of discipline-specific standards guiding forensic science practices. To this end, the OSAC facilitates the development of discipline-specific forensic science standards and guidelines that can be further developed and published by Standards Developing Organizations (SDOs). OSAC also evaluates standards for placement on the OSAC Registry, which serves as a central repository of consensus-based standards that have been deemed high quality and technically sound. The Academy Standards Board (ASB) was established by the AAFS in 2015 as an ANSI-Accredited SDO. Both organizations are comprised of volunteer practitioners and other stakeholders with a vested interest in standards and best practices applicable to the friction ridge discipline. This is a collaborative relationship in which documents created by the OSAC Friction Ridge Subcommittee (FRS) are passed to the ASB Friction Ridge Consensus Body (FRCB) for the standards development process, after which they are considered for inclusion on the OSAC Registry.

During this presentation, updates related to friction ridge standards development activities will be presented. These include: (1) standards and guidelines that have been proposed by the OSAC FRS and currently being evaluated and further developed through the ASB FRCB; (2) standards and guidelines that have been published by the ASB and being considered for the OSAC Registry; (3) standards and guidelines published by the ASB that have been placed on the OSAC Registry; (4) documents currently in development by the OSAC or by the ASB; and (5) priorities for new documents or work products by the OSAC FRS or by the ASB FRCB.

This presentation will also highlight how the process of moving documents back and forth between the OSAC and ASB works for the friction ridge discipline, challenges and successes that process has encountered, and what the near future looks like for the promulgation of friction ridge standards and guidelines.

B110 Advancing the Understanding of 3D Imaging for Firearms Identification

Melissa Nally, BA, Houston Forensic Science Center, Houston, TX; Heike Hofmann, PhD*, University of Nebraska- Lincoln, Lincoln, NE; Alicia L. Carriquiry, PhD, Iowa State University, Ames, IA; Jeffrey J. Salyards, PhD, CSAFE, Ames, IA; Donna B. Eudaley, BS*, Houston Forensic Science Center, Houston, TX; Preshious Rearden, PhD, Houston Forensic Science Center, Houston, TX*

Learning Objectives: This presentation will allow the attendees to understand the challenges of sharing 3D scans generated from different systems with respect to firearms identification. Solutions for overcoming these challenges will also be shared.

Impact Statement: The presentation will provide insight into 3D imaging technology and the ability for firearm examiners to share 3D scans electronically. This would eliminate the need for physical transfer of evidence, which can save time and resources.

Abstract Text: One of the newest emerging technologies in forensic firearms identification is three-dimensional (3D) scanning technology, which produces a 3D surface scan that can be rendered into a viewable image. As with all new technology, it is important to understand the performance capabilities and limitations of the technology. At present, most 3D instruments on the market use differing scanning technologies, but all can export scans as X3P (XML 3D Surface Profile) files.[1] In principle, the data and images of bullets and/or cartridge cases generated by the different 3D systems should be interchangeable using the X3P format, but this inter-compatibility has not been demonstrated.

The overall goal of this research is to understand the challenges that arise when sharing 3D files for firearm identification between forensic crime laboratories. A study was conducted to test the compatibility of data and images between three of the most widely used vendors of 3D instrumentation. Through collaborations with 3D vendors, the study focused on 3D instruments (and associated software) manufactured by Cadre (TopMatch), Leeds (Evofinder), and LeadsOnline/Ultra FT (Quantum).

Initial results showed that the X3P files were not compatible across the different 3D platforms. Upon further analysis, we discovered that while the exchange format X3P is an International Organization for Standardization (ISO) standard (ISO 25178-72), not all the vendors were using the newest form of the standard and there were some ambiguities in the interpretation of the standard. These differences between the file formats created unexpected hurdles in the actual exchange of X3P files between different systems' software. Based on the initial findings, the vendors agreed to make modifications to their software platforms to enable interoperability.

This presentation will focus on the software modification process and other factors discovered while sharing the 3D files. By resolving the inter-compatibility issues, we were able to concentrate on the feasibility of sharing 3D scans across forensic crime laboratories for virtual visual comparisons. The preliminary findings of the virtual visual comparison study will also be presented.

B111 Accuracy, Efficacy, and Reproducibility of Muzzle-to-Target Distance Determination Using Gunshot Residue

R. Austin Hicklin, PhD, Noblis, Reston, VA; Nicole M. Richetelli, PhD*, Noblis, Reston, VA*

Learning Objectives: This presentation will provide the first public presentation of results from a study assessing the accuracy, efficacy, and reproducibility of forensic examiners when estimating Muzzle-to-Target Distance (MTD) using Gunshot Residue (GSR). After attending this presentation, attendees will learn about the accuracy and reliability of distance determinations made by forensic examiners.

Impact Statement: This presentation will communicate information from a study assessing the accuracy, efficacy, and reproducibility of forensic examiners when estimating muzzle-to-target distance using GSR. These results may be used by practitioners, laboratory managers, standards organizations, and the legal community to assist in decision making, improving procedures and training, and highlighting areas for potential standardization.

Abstract Text: How accurate and reproducible are muzzle-to-target distance determinations made by forensic examiners using GSR? GSR MTD determinations are frequently used in casework, particularly in shooting reconstructions, death investigations, and investigations of police-involved shootings. In death investigations, GSR MTD can be used in an assessment of whether a gunshot death may be considered suicide or homicide or to provide evidence in gunshot deaths that are claimed to be in self-defense. Despite their utility in operational casework, the accuracy, efficacy, and reproducibility of MTD determinations by forensic examiners using GSR have not been systematically and rigorously assessed. This lack of discipline-specific research leaves a notable gap in the scientific basis for court acceptance and expert testimony in legal proceedings, which is a significant concern for the criminal justice system.

This study is being conducted as a rigorous "black box" evaluation of GSR MTD determinations by practicing examiners, assessed in terms of accuracy (correctness), efficacy (reporting distances with ranges that are specific enough to be effective), and reproducibility (inter-examiner consistency). The study design is based on the authors' experience and lessons learned in conducting black box studies evaluating forensic examiners in multiple disciplines.[1-10] This National Institute of Justice (NIJ) -funded study (Grant # 15PNIJ-23-GG-04222-MUMU) is being conducted by Noblis, with extensive assistance from a working group of subject matter experts.

In addition to the black box study, this project will: (1) collect a GSR MTD reference sample dataset, which will be publicly released at the conclusion of the study; (2) conduct an assessment of the degradation of GSR samples over weeks or months under various conditions; and (3) work with subject matter experts to develop a report of GSR MTD recommendations with particular focus on implications regarding existing and proposed standards, standard operating procedures, training, and quality assurance.

This lecture will be the first public presentation of the results of this study. This study is being conducted to provide essential information to laboratory managers, practitioners, and the legal system regarding GSR MTD, including an understanding of the capabilities, variability, and limits of GSR examiners; the associations between GSR examiners' performance and their training and experience; and the extent to which MTD determinations are accurate and can be reproduced by a second examiner. The results of this study will provide empirical data that may also be used to assist the GSR community in the development of standards and best practice recommendations regarding MTD determinations, and that may be used to augment training programs.

B113 The AFTE Procedural Support Committee

Jennifer Floyd, BS, Arkansas State Crime Laboratory, Little Rock, AK*

Learning Objectives: Attendees of this presentation will learn about the newly created Association of Firearm and Toolmark Examiners (AFTE) Procedural Support Committee (PSC) and how this committee can assist them.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of a new committee designed to assist firearm and toolmark examiners, crime lab administrators/Quality Assurance (QA) managers, and accreditation organizations with questions regarding procedural, technical, accreditation, and QA issues.

Abstract Text: The AFTE Board of Directors and President created the PSC to assist Firearm and Toolmark Examiners, crime lab administrators/Quality Assurance (QA) managers, and accreditation organizations when questions involving accreditation, assessment findings, validations, standard operating procedures, and other quality assurance issues come up. The PSC is poised to respond rapidly and confidentially to questions with a knowledgeable staff, allowing all parties to obtain timely and helpful information.

This presentation will inform attendees about this committee and provide examples of what the committee can help accomplish. Examples include the following:

(1) Laboratories can receive guidance when facing a QA issue, accreditation matter, or an assessment finding. They may contact this committee's membership, outline the issues, and obtain a potential solution or information to help resolve the scenario. While assessors are unable to provide methods to resolve observed conflicts and findings during an assessment, this committee may be your authoritative lifeline for a rapid solution. The committee members may be able to provide a solution or remediation they have already enacted or encountered previously.

(2) Assessors and accreditation bodies can gain national (and international) perspectives on problems and interpretations, either preemptively or during their assessments, as our team is purpose-built and poised to respond rapidly and confidentially to questions.

(3) QA managers can use this AFTE committee's extensive knowledge to obtain relevant, practical, experience-based assistance relating specifically to the discipline of firearm and toolmark examination. The committee can provide actionable feedback regarding validations, Standard Operating Procedures (SOPs), and any information that may be vital to building a firearm identification unit or addressing quality assurance matters too complicated to resolve in-house.

(4) Laboratories preparing for an initial accreditation (17025 or 17020) may contact this committee in order to thoroughly prepare their firearm and toolmark units for the process.

B114 OSAC/ASB Standards Development Activities in Firearm and Toolmark Examination

Rebecca LoBalbo, MPA, Arkansas State Crime Laboratory, Little Rock, AR; Jennifer Floyd, BS, Arkansas State Crime Laboratory, Little Rock, AR*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the work of the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) Subcommittee and the American Academy of Forensic Sciences (AAFS) Academy Standards Board (ASB) Consensus Body for Firearms and Toolmarks and know the status of those discipline-specific standards.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to firearms and toolmarks focusing on the collaborative efforts of the NIST OSAC and the AAFS ASB on those standards.

Abstract Text: The OSAC for Forensic Science was created by the NIST to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC draft standards are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards. The OSAC Firearms and Toolmarks Subcommittee is comprised of over 20 experts in the field from crime laboratories, academia, and government agencies. Its work includes the comparison of microscopic toolmarks on bullets, cartridge cases, and other ammunition components as well as firearm function testing, serial number restoration, muzzle-to-object distance determination, and forensic examination of tools and toolmarks.

The ASB was formed by the AAFS and is recognized as a SDO to accomplish the task of completing and publishing Standards, Best Practice Recommendations, and Technical Notes. The Firearms and Toolmarks Consensus Body (CB) was created by the ASB. The Firearms and Toolmarks CB is comprised of representatives of the various stakeholders in the firearms and toolmarks forensic discipline. It includes analysts, academics, prosecution and defense lawyers, industry representatives, and related forensic scientists. The Firearms and Toolmarks CB meets regularly and has done so over the past ten years. The CB does most of its work through committees that meet on specific work proposals. Those proposals generally are originated by the Firearms OSAC, which promulgates draft standards. The CB reviews the proposed draft standards, submits them for rigorous discussion and review by the relevant committee members and by the CB itself. The proposed standards are then circulated for public comment and often return for several rounds of discussion and revision.

During this presentation, updates related to firearms and toolmark evidence will be discussed. These include: (1) recent standards that have been added to the OSAC Registry; (2) OSAC-proposed standards; (3) published standards from the ASB that have yet to go through the Registry approval process; (4)documents currently in development at the OSAC or by the ASB; and (5) priorities for new documents or work proposals, and other highlights.

B115 Investigation of the Secondary Transfer of GSR From a Shooter to Common Inanimate Objects

Brittany S. Claassen, MS, Harris County Institute of Forensic Sciences, Houston, TX; Charley Cross, BS, Jackson State University, Rosharon, TX; Kim Kunkler, PhD, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: This presentation summarizes the findings from a primer Gunshot Residue (GSR) transfer study designed to investigate the degree of secondary transfer that can occur when a known shooter handles an inanimate object. Attendees of this presentation will become familiar with the potential for transfer of GSR from a shooter to several types of inanimate objects, and they will gain an appreciation for the role of surface texture in the degree of secondary transfer.

Impact Statement: This research will impact the forensic science community by providing additional information about the secondary transfer of GSR from a shooter to common inanimate objects of various surface textures. This study addresses portions of an identified need within the forensic community, and the study findings can assist stakeholders in their interpretations of the results provided by GSR analysts.

Abstract Text: The secondary transfer of primer GSR from a shooter to another person or object is a matter of concern for many forensic stakeholders, and GSR analysts are routinely asked about it in relation to the interpretation of their results.

This study aimed to address questions related to the degree of secondary transfer of GSR from a shooter to common inanimate objects composed of different materials. It was hypothesized that the degree of secondary transfer is dependent on the texture of the material, with a higher degree of secondary transfer when the item has a rough or porous surface.

To test this hypothesis, replicates of five different types of inanimate objects with varying surface textures (aluminum can, plastic bottle, office paper, 100% cotton shirt, and a 60%/40% cotton/polyester blend shirt) were systematically handled by shooters immediately after firing three rounds of 9mm Luger PMC Bronze 124 grain ammunition using Glock brand firearms. The handled items were then sampled using a commercially available carbon adhesive stub designed for GSR collection. Analysis of the stubs for samples taken before and after handling the items, the sampler's hand blank stubs, and control stubs was performed using Scanning Electron Microscopy/Energy Dispersive X-Ray Spectroscopy (SEM/EDS) with a commercially available automated software package capable of detecting characteristic GSR particles. For each stub, all candidate three-component (lead, barium, and antimony) particles detected by the automated analysis were counted. Manual reacquisition was performed on each initial, presumptive positive stub to confirm up to ten particles with compositions characteristic of GSR.

A total of 75 stubs were collected and analyzed across the five inanimate object types. Over the course of this study, every stub obtained from an inanimate object following handling by a known shooter had at least two characteristic GSR particles on it. Furthermore, both the average number of candidate particles detected and the average number of characteristic GSR particles confirmed were higher for samples obtained from the objects with rougher/more porous surfaces (paper and shirts) than for the samples obtained from the objects with smoother/non-porous surfaces (aluminum cans and plastic bottles). These findings can help guide stakeholders' interpretations of the results provided by GSR analysts, and they will form the foundation for a future study involving tertiary transfer.

B116 An Evaluation of Barrel Wear Caused by Polymer-Coated Ammunition

Eden Amin, BS/BA, University of Central Oklahoma, Allen, TX; Eric Law, PhD, University of Central Oklahoma, Edmond, OK; James P. Creecy, PhD, University of Central Oklahoma, Edmond, OK; Stephanie Luehr, MS, SCL Forensics, Houston, TX*

Learning Objectives: After attending this presentation, attendees will understand how polymer-coated bullets influence barrel wear and toolmark degradation and how this affects the reliability of forensic firearm identification using modern Glock Marksman Barrels (GMBs).

Impact Statement: This presentation will impact the forensic science community by addressing concerns over the increasing use of Total Synthetic Jacket (TSJ) ammunition and its potential to obscure or alter identifying marks critical to bullet comparison. Understanding these effects is essential as both law enforcement and civilian use of TSJ rounds become more widespread.

Abstract Text: Forensic firearm analysis resides on the principle that each firearm is capable of imparting individual characteristics on ammunition components. Individual characteristics can then be used to link a bullet or cartridge case back to the firearm which shot it. However, the persistence of these individual characteristics can be influenced by both ammunition type and barrel wear over time. Although various types of ammunition are available to shooters today, polymer-coated ammunition, such as Federal TSJ ammunition, have recently gained popularity for their potential to reduce lead exposure and firearm fouling. However, forensic implications of TSJ ammunition remain under-researched, particularly regarding their impact on barrel wear and the visibility of individual toolmarks used for firearm identification.

This study compares the effect of polymer-coated (TSJ) bullets to traditional Full Metal Jacket (FMJ) bullets on barrel wear and forensic traceability over the course of 500 shots. Two GMBs were tested in a Glock 19 Gen 5 pistol and fired under controlled conditions with one barrel firing 500 traditional FMJ rounds only and the other firing 500 TSJ rounds. Every tenth bullet from each barrel will be recovered in sequence using a ballistic rubber-based bullet trap and scanned using a Cadre Forensics TopMatch GS 3D system. Bullets will be analyzed using the Cadre Forensics implementation of the National Institute of Standards and Technology (NIST) Congruent Matching Profile Segments (CMPS) algorithm to assess the persistence of striations over the course of 500 shots through each of the two barrels.

It is hypothesized that the experimental barrel will possess increased striation clarity, likely due to reduced metal on metal contact as a result of firing TSJ bullets. By contrast, the control barrel is expected to possess decreased striation clarity as a result of the successive firing of FMJ bullets that produce significant metal on metal contact. This research aims to illustrate any potential evidentiary limitations posed by TSJ ammunition and highlights the importance of evaluating ammunition type when performing forensic firearm comparisons.

B117 A Quantitative Analysis of Full and Partial Shotgun Pellet Patterns for Distance Determination

Jamison Trimber, BS, Virginia Commonwealth University, Richmond, VA; Stephanie Walcott, MScFS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: After attending this presentation, attendees will be able to recognize current practices of firearm analysts when determining distances for full and partial shotgun pellet patterns. Attendees will also be introduced to novel uses of ImageJ in the forensic science field and its utilization for shotgun pattern analysis.

Impact Statement: Advancing objectivity and standardization in forensic firearms analysis is essential for strengthening the scientific foundation of the discipline. This presentation introduces a novel quantitative method for analyzing partial shotgun pellet patterns and offers a robust replacement for the current semi-quantitative approach used in full pattern analysis. By enabling statistically rigorous evaluation, this method provides new insights into a long-standing debate: whether a specific suspect firearm is necessary for valid shotgun pellet pattern distance determinations, or if a firearm of the same make and model with identical ammunition can yield scientifically reliable results. The findings have the potential to enhance methodological consistency and inform best practices across forensic laboratories.

Abstract Text: Shotguns are long-barreled firearms that discharge multiple projectiles (pellets or "shot") or a single slug. Upon firing, pellets disperse from the muzzle and create a characteristic spread pattern on the target. The configuration of this pattern is influenced by multiple variables, including barrel length, choke type, ammunition characteristics, and muzzle-to-target distance.[1] When a complete pellet pattern is present, forensic firearm examiners typically compare test patterns to the questioned pattern to estimate the shooting distance.[2] Current practices often require the use of the specific suspect firearm to generate test patterns, based on the belief that only the original weapon can produce scientifically valid comparisons.[2] This can lead to investigative challenges when the suspect firearm is unavailable for testing.

This study addresses two primary objectives. First, it builds upon and validates a previously developed quantitative method using ImageJ, an open-source image analysis software, to measure pellet-to-pellet distances in both full and partial shotgun pellet patterns.[3] This approach provides pixel-level precision in spatial measurements, offering a more objective and reproducible method for estimating muzzle-to-target distances.[3] Second, the study uses this method to evaluate a long-debated question in the field: whether the use of a firearm of the same make and model, loaded with identical ammunition, can yield statistically equivalent results to those obtained using the original suspect firearm.

The findings support the potential for this quantitative technique to reduce examiner subjectivity and broaden the applicability of distance determination methods, especially in cases where the suspect firearm is unavailable. Ultimately, this research contributes to the advancement of standardized, evidence-based practices in forensic shotgun pattern analysis.

B118 A Handcrafted Pen Gun Suicide: A Case Report

Quentin Rébillard, MD, Forensic Medicine Department, EPDFM, Chu of Montpellier, Montpellier University, Montpellier, Languedoc-Roussillon, France; Christian Brocard, PhD, Forensic Medicine Department, EPDFM, Chu of Montpellier, Montpellier University, Montpellier, Languedoc-Roussillon, France; Laurent Martrille, MD, PhD, Forensic Medicine Department, EPDFM, Chu of Montpellier, Montpellier University, Montpellier, Languedoc-Roussillon, France; Emmanuel Margueritte, MD, Forensic Medicine Department, EPDFM, Chu of Montpellier, Montpellier University, Montpellier, Languedoc-Roussillon, France; Clarisse Dubois, MD, Forensic Medicine Department, EPDFM, Chu of Montpellier, Montpellier University, Montpellier, Languedoc-Roussillon, France; Elise Arbefeuille, MD, Forensic Medicine Department, EPDFM, Chu of Montpellier, Montpellier University, Montpellier, Languedoc-Roussillon, France*

Learning Objectives: After attending this presentation, participants will understand the critical role of collaboration between forensic physicians and ballistic experts in crime scene investigations. They will also recognize the importance of meticulous attention to detail during scene analysis to ensure the integrity and accuracy of forensic findings but also the security of the professionals working on the scene.

Impact Statement: This case illustrates the critical importance of thorough autopsy and interdisciplinary collaboration, reminding us that foundational forensic practices—careful observation, reproducible experimentation, and teamwork—remain essential tools when confronted with unconventional cases. As forensic science evolves, this investigation reaffirms the value of returning to core principles to ensure robust and accurate medicolegal conclusions.

Abstract Text: Very few cases involving concealed weapons like pen guns have been reported nationally and internationally, and lethal outcomes are exceptionally rare. One such fatal case occurred at the Institute of Legal Medicine of Montpellier in late 2022.

The decedent was a 54-year-old man who was fatally shot on the left side of his chest. The entrance wound exhibited characteristics consistent with a contact-range gunshot and measured 14 x 15 mm. The wound was perforating, following a front-to-back and slightly downward trajectory. On its path, the projectile perforated and lacerated the left lung and the left ventricle of the heart, causing associated pericardial and pleural hemorrhages, and exited through the back. These injuries were fatal, and death occurred within minutes, with no possibility of medical intervention. The autopsy concluded that the cause of death was a gunshot wound and the manner of death was most likely suicide

The weapon found at the scene was a handcrafted pen gun. The device was constructed from a flare launcher pen fitted with a .22 Long Rifle (LR) barrel.

The entrance wound was unusually wide for a .22 LR caliber projectile, prompting test firings to reproduce and compare wound dimensions. These were performed at the Scientific Police Laboratory's shooting range in Toulouse, France, using a similar handcrafted pen gun from their forensic collection. Six shots were carried out: two at contact range with .22 LR ammunition from two brands (FEDERAL and ELEY), followed by four shots at distances of 5, 10, 20, and 50 cm using FEDERAL rounds. Synthetic leather targets were stretched over wooden boards to approximate soft tissue.

The largest entrance wound from the test series was produced by the FEDERAL contact shot, measuring 24×15 mm, while the contact shot with ELEY ammunition measured 13×15 mm. All other shots created typical entrance wounds approximately 3×3 mm, except the one at 50 cm, which deviated in trajectory. These test results were consistent with the fatal wound observed in our case (15×14 mm).

Homemade pen guns are rarely discussed in forensic literature, and this case represents the first account of a fatality involving such a weapon in France. Despite being prohibited, this case illustrates the need for stronger regulation of concealed or disguised weapons. It also highlights the forensic value of meticulous external examination at the scene and underline the importance of collaboration between forensic pathologists and ballistics experts. Understanding the wound mechanics of improvised devices is critical in evaluating cause and manner of death in cases involving unconventional weaponry.

B119 A Comparison of Solid Phase Microextraction and Purge and Trap Methods for Measuring VOCs Emanating From Lithium-Ion Batteries and Electronic Media

Samuel DeNight, BS, George Mason University, Manassas, VA; Edward Bentil, PhD, George Mason University, Manassas, VA; Brian Eckenrode, PhD, George Mason University, Manassas, VA*

Learning Objectives: This presentation will provide information on how different sampling methods are used and the various advantages/disadvantages of each for quantitative Volatile Organic Compounds (VOCs) analysis. In addition, the importance of using a variety of Solid-Phase Microextraction (SPME) fibers when sampling lithium-ion batteries will be shown. For each method, information on how to properly quantify compounds that have been qualitatively identified in samples will be provided.

Impact Statement: Competence/ability: Attendees will obtain an understanding of the steps in quantification of VOCs and why it is necessary to achieve this data. Performance: Using this data will allow future quantification of the VOCs present to appropriately train canines for field investigations.

Abstract Text: Lithium-ion batteries are widely used in devices such as smart phones and laptops, but they present safety risks due to their potential to catch fire when overheated or exposed to moisture.[1] Screening for these batteries in airports may become necessary for future airline travel. Detection canines are currently trained to locate lithium-ion batteries, though the specific VOCs and the levels of the VOCs triggering these alerts remain unclear. While training aids have been developed, their effectiveness has been inconsistent. This study seeks to identify and characterize VOCs released from both actual lithium-ion batteries, electronic media, and commercially available training aids using Gas Chromatography/Mass Spectrometry (GC/MS).

Multiple types of lithium-ion batteries were analyzed, and each battery was stored in an appropriately sized jar for at least one month to allow VOCs to build up in the headspace. Three headspace sampling methods were used: direct injection, purge and trap, and SPME. Samples were introduced into an Agilent 7890A GC coupled to a 5975C inert XL MSD scanning from m/z 30 to 300.

For the purge and trap technique, nitrogen gas was used to move VOCs emanating from a battery into an adsorbent tube filled with the adsorbents Carbopack C, Carbopack B, and Carbosieve III. The sample was then transferred to the GC column using a Gerstel Thermal Desorption Unit (TDU). The GC oven temperature started at 40°C (hold for one minute), increased at 3°C per minute to 60°C, and then rapidly ramped at 30°C per minute to a final temperature of 250°C.[2] Helium served as the carrier gas with a flow rate of 1 mL/min through an HP-5MS column.

Diethyl carbonate was identified in the headspace of a pair of unpackaged 9V lithium-ion batteries via both direct gas injection using a 10 µL gas-tight syringe and SPME.[3,4] The SPME fiber used a combination of carboxen, divinylbenzene, polydimethylsiloxane, and an acrylate phase, confirming the presence of the same compound. Purge and trap results will also be presented.

A disk-shaped training aid was analyzed by placing it in a sealed Tedlar bag. The headspace was sampled using both direct injection and SPME. Two compounds (2,4-dimethylhexane and nonanal) were identified via National Institute of Standards and Technology (NIST) library searches. These compounds are typically associated with human decomposition, suggesting that the training aids may not emit VOCs representative of actual lithium-ion batteries. This aligns with observations from canine handlers, who noted that dogs alerted to real batteries but not to the training aids during warehouse searches.

Analysis was also conducted on the headspace over several CR-2032 lithium-ion button batteries via direct injection with no observable compounds; however, analysis of these batteries via static and dynamic SPME was successful. The headspace over a variety of these lithium-ion containing batteries has been analyzed also by purge and trap methods and the data will be presented.

B120 Crystals Under the Lens: A Microscopical and Micro-Raman Analysis of Inorganic Oxidizers in Pyrotechnic-Based IEDs

Carissa Burton, BS, Sam Houston State University, Huntsville, TX; Jared Estevanes, PhD, Microtrace LLC, Elgin, IL; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will gain an understanding of the advantages and limitations of combining Polarized Light Microscopy (PLM) with micro-Raman spectroscopy for identifying various types of inorganic salts commonly found in pyrotechnic-based Improvised Explosive Devices (IEDs), both pre- and post-blast, through their recrystallization from water.

Impact Statement: This presentation will impact the forensic science community by demonstrating the effectiveness of an analytical approach that integrates techniques already available in forensic laboratories, namely PLM and micro-Raman spectroscopy, for the analysis of recrystallized inorganic oxidizing salts from post-blast pyrotechnic pipe bombs. In addition, this study aimed to highlight a practical implementation of the recommendations outlined in Organization of Scientific Area Committees' (OSAC's) 2022–S-0023 "Standard Practice for the Forensic Analysis of Explosives by Polarized Light Microscopy," specifically focusing on the identification of recrystallized inorganic constituents in explosive residues.

Abstract Text: The United States Bomb Data Center reported that in 2023, 59 out of 224 explosions were caused by pyrotechnics/fireworks. The continued prominence of consumer fireworks being used as the explosive charge in IEDs has led to the need to better understand their composition to assist practitioners in their rapid analysis and identification. Additionally, research addressing the detection of inorganic oxidizing salts from fireworks after deflagration using analytical methods other than ion chromatography or Scanning Electron Microscopy with Energy-Dispersive X-Ray Spectroscopy (SEM/EDS) is limited. This study, therefore, aimed to demonstrate the efficiency of an analytical scheme combining light microscopy and micro-Raman spectroscopy that trace evidence analysts can utilize to identify and differentiate inorganic oxidizing salts in a post-blast scenario.

Two Polyvinyl Chloride (PVC) pipe bombs, made from the same 2.0 oz pyrotechnic mixture containing various fireworks, were constructed with the assistance of the Texas Montgomery County Fire Marshal's Office (TMCFMO). The pipe bombs, alongside ten witness materials, including wood, electrical tape, a cell phone, batteries, and nuts and bolts, were placed in a polypropylene toolbox to simulate a bombing scenario. Inorganic salt standards for potassium perchlorate (KClO4), potassium nitrate (KNO3), and barium nitrate (Ba(NO3)2) were recrystallized directly from water while the intact pyrotechnic mixture was recrystallized using a decantation method. Wet and dry swabbing techniques were employed and compared to determine the optimal method for recovering inorganic compounds in post-blast debris. The water recrystallization method was followed by *in situ* analysis using micro-Raman spectroscopy, which targeted euhedral and subhedral crystals directly on the glass slide to support optical crystallographic identifications with direct spectroscopic data.

Using PLM and micro-Raman spectroscopy, all observed crystals were identified, albeit with certain limitations. The low concentration of inorganic oxidizers remaining after the explosion hindered the formation of euhedral crystals for all analytes. Several inorganic oxidizers were identified in the post-blast fragments, including KClO4, KNO3, and Ba(NO3)2. While KNO3 was more difficult to detect compared to KClO4 when using PLM alone, the implementation of micro-Raman spectroscopy nevertheless enabled its identification. Additionally, the water recrystallization technique influenced the resulting Raman spectra, showing decrease peak intensity and increase in band width; however, it did not ultimately affect the accurate identification of the salts using micro-Raman spectroscopy. The findings demonstrated that the integrated use of PLM and micro-Raman spectroscopy enabled the identification of inorganic oxidizing salts in a post-blast context while also outlining the strengths and limitations associated with this analytical approach.

B121 Evaluating Line Illumination Sampling of a Hand-Held Raman Spectrometer for Detecting Hydraulic Fluid Contamination in Jet Fuel

Megan Linson, BS, Sam Houston State University, Huntsville, TX; Javier E. Hodges, BS, Sam Houston State University, Huntsville, TX; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: Attendees will learn how line illumination sampling affects the spectral resolution of a hand-held Raman spectrometer. The ability of the spectrometer to detect hydraulic fluid contamination in jet fuel was evaluated and compared to another hand-held Raman spectrometer using a Rapid Laser Spin (RLS). Participants will gain insight into differences in spectral quality, data analysis, and practical usability for forensic field applications.

Impact Statement: By comparing the performance of line illumination sampling with other methods, forensic and military practitioners will gain valuable insights into the capabilities and limitations of hand-held Raman spectroscopy devices for analyzing jet fuel and hydraulic fluid. This comparison helps guide the selection of instruments for field-based chemical identification and contamination detection, ultimately enhancing the accuracy and reliability of forensic evidence evaluation.

Abstract Text: This study compares the performance of two hand-held Raman spectrometers, with different laser sampling designs, in detecting contamination of jet fuels with various hydraulic fluids. Five types of jet fuel were spiked with six hydraulic fluids of differing chemical bases, including synthetic polyalphaolefins (PAO)-based fluids (83282D, 87252C), a synthetic hydrocarbon base fluid (87257C), a phosphate ester (HyJet IV-A), petroleum-based (5606H), and mineral-based (5606J) fluids. Raman spectra were collected using a standardized integration time and preprocessing workflow.

Principal Component Analysis (PCA) was used to evaluate spectral clustering for each fluid–fuel combination across both instruments. Initial PCA results from the line illumination sampling spectrometer guided the selection of test combinations of contamination levels. These combinations were subsequently tested on the spectrometer with RLS sampling to evaluate its sensitivity, reproducibility, and comparability.

Preliminary results show distinct spectral differences between the two instruments for the same fluid–fuel mixtures, with the RLS sampling exhibiting weaker separation in some cases. This suggests that despite internal consistency, the instruments are not directly interchangeable without calibration adjustments. The findings highlight the importance of fluid selection and matrix matching when using portable Raman tools for fuel contamination screening in field settings.

Beyond instrument performance, this study also considers practical constraints of field use, such as user interface design, data export capabilities, and acquisition time. While the line illumination sampling system offers greater spectral detail and resolution, it requires external software and a connected laptop, which limits its portability. The RLS sampling system was more user-friendly and self-contained but may underperform in detecting subtle contamination unless carefully calibrated. These findings highlight the importance of selecting the appropriate laser sampling techniques and matching the sample matrix when using portable Raman tools for contamination screening. The findings also demonstrated that the performance of hand-held Raman spectrometers can vary significantly even under identical measuring conditions. As such, users must account for device-specific capabilities when designing workflows for forensic screening, fuel quality control, or environmental field investigations.

B122 Optimizing Explosives Detection: How Burial Medium and Moisture Influence Ammonium Nitrate Vapor Transport

Joel L. Fuentes Carrasco, BS, Florida International University, Hialeah, FL; Emma Calabrese, PhD, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL; Lindsay D. Waldrop, PhD, Chapman University, Orange, CA*

Learning Objectives: Attendees will learn how environmental factors influence the detection of Ammonium Nitrate(AN) -based explosives after burial and understanding the transport of ammonia vapor, from the ammonia nitrate, through simulated burials. Attendees will leave with practical insight into adapting canine detection techniques to varying environmental conditions.

Impact Statement: The findings of this research will inform Explosive Detection Dog (EDD) teams of limitations associated with detecting and removing buried explosives. Understanding how external conditions—such as rainfall—affect detection of AN-based explosives in sand or soil will directly enhance training and operational strategies used by EDD teams.

Abstract Text: Homemade Explosives (HMEs) have been featured in armed conflicts for nearly a century. AN's commercial availability makes it the oxidizer of choice in many HMEs, and 23 countries reported Antipersonnel Landmines (APLs) built with HME charges. In 2023, at least 5,757 people were killed or injured by landmines or explosive remnants of war; improvised APLs caused 2,071 of those casualties—about 36 percent.[1] Although no global figure exists, multiple United States government reports from the Afghan conflict estimate that 70–80 percent of HMEs contained AN.[2] HME variability complicates detection. Explosive-detection dogs are outstanding biosensors, yet they must generalize across differing AN formulations and fuel mixes. A recent study found that standard training protocols yielded only a 56 percent detection rate for surface-laid AN charges—performance likely to drop further once the explosives are buried.[3] Preliminary results indicated that dry conditions suppress ammonia-vapor release—especially in soil, whose complex matrix offers greater sorption sites—whereas added moisture enhances AN volatilization through evapotransport, promoting upward migration of vapor that can reach the headspace for detection.

To better understand the vapor transport of AN in soil and sand, an experimental chamber was designed to simulate the burial of HMEs under controlled laboratory conditions. The chamber features four ports for headspace sampling at various vertical positions. AN in prill form was placed inside a Training Aid Delivery Device (TADD), which served as the container for the buried explosive. Solid Phase Microextraction (SPME) coupled with derivatization using butyl chloroformate was employed for sampling, and Gas Chromatography/Mass Spectrometry (GC/MS) was used to semi-quantitatively detect ammonia vapor. This study tested the hypothesis that AN vapor transport is influenced by the burial medium (sand vs. soil), with losses attributed in part to sorption, and that environmental conditions such as moisture content further impact detection. AN was buried for 24 hours in both sand and soil under dry and moist conditions to allow for equilibration of headspace. Sampling was conducted in triplicate to assess reproducibility and environmental impact on vapor detection. Results showed that AN was detected far more readily in moist sand than in dry sand, and the same pattern held for soil. The enhanced detectability under moist conditions was likely due to AN's high water solubility: once dissolved, the compound could migrate and partition into the vapor phase more efficiently, thereby increasing the concentration of detectable ammonia at each sampling port. The findings of this research will inform EDD teams how rain and the burial medium affect their ability to locate AN devices, guiding improvements in training and field tactics.

B123 Rapid Spectrophotometric Identification of Peroxide-Based Explosives Using a Modified Iodometric Method

Alana R. Connor, Cedar Crest College, Manassas, VA; Marianne Staretz, PhD, Ceadr Crest College, Allentown, PA*

Learning Objectives: After attending this presentation, participants will learn how a modified iodometric assay can be used to identify and quantify peroxide-based explosives like TATP and HMTD. They will also gain insight into the advantages of this method in terms of sensitivity, simplicity, and field application.

Impact Statement: This research will enhance forensic scientists' abilities to detect and quantify peroxide-based explosives quickly and reliably using cost-effective chemistry. By combining sensitivity and simplicity, it can improve forensic science workflow and public safety, especially in resource-limited environments.

Abstract Text: Peroxide-Based Explosives (PBEs) have been used in many bombings over the past decade due to their accessibility, high explosive potential, and ease of synthesis from over-the-counter materials.[1] One such example is the coordinated 2019 attacks in Sri Lanka, which resulted in over 250 deaths.[2] Despite this and many other deadly bombings across the world, current detection and quantification methods for PBEs are often limited by complex instrumentation, high cost, or challenges in sample stability.

The proposed method leverages the redox properties of peroxides, which oxidize iodide to iodine in acidic solution. The liberated iodine forms a triiodide complex that absorbs strongly in the Ultraviolet (UV) -visible spectrum, allowing for sensitive spectrophotometric quantification.[3] The procedure involves acidification with Hydrochloric Acid (HCl), followed by the addition of potassium iodide (KI). The sample was then placed in a temperature-controlled water bath, and the results were collected at three wavelengths: 352 nm, 420 nm, and 288 nm. Calibration curves were generated using TATP in 7 µM increments from 7 to 35 µM and HMTD in 3 µM increments from 3 to 15 µM. The method demonstrated a Limit Of Detection (LOD) of 0.37 µM for TATP and 1.2 µM for HMTD, while the Limit Of Quantification (LOQ) was 1.1 µM for TATP and 3.5 µM for HMTD. Average Relative Standard Deviations (RSD) were 5.5% for TATP and 5.9% for HMTD, calculated across all tested concentrations. No signal was observed with non-peroxide explosives, which confirms the method's selectivity.

This modified iodometric technique offers several key advantages compared to other detection methods: it is rapid, requires no advanced instrumentation, and is easily adaptable for use in both traditional laboratory settings and potential field applications. These features make the method highly valuable for forensic laboratories, Explosive Ordnance Disposal (EOD) teams, and investigators working in resource-limited environments or time-sensitive situations.

Overall, this work highlights the utility of classical wet chemistry approaches—when appropriately adapted—for modern forensic applications. By bridging the gap between sensitivity and accessibility, this method contributes to improved screening and analytical capabilities for peroxide explosives, ultimately supporting public safety and enhancing forensic response to chemical threats.

B124 The Application of Deep Learning in Source Attribution of Ignitable Liquid Residues in Fire Debris for Forensic Fire Investigation

Ting-Yu Huang, PhD, Central Police University, Taiwan, Guishan Dist., Taoyuan, Taiwan; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: From this presentation, attendees will learn the application of deep neural networks that operate effectively with limited training data, enabling them to identify complex patterns in chromatographic data for source attribution of Ignitable Liquid (IL) residues. A practical example demonstrating how to discriminate gasoline brands in fire debris samples will be illustrated and discussed in this presentation.

Impact Statement: This study aims to present an analytical approach that delivers consistent results across different investigators to support source attribution accurately, quickly, and automatically, enhancing investigative leads in crime case investigations.

Abstract Text: In fire investigation, chemical attribution techniques focus on identifying the source of ILs in fire debris collected from the scene. This step is essential because it could link ILs to specific gas retailers or suspect activities, providing vital clues for criminal investigations. The current gold standard for analyzing ILs in fire debris samples involves using Gas Chromatography/Mass Spectrometry (GC/MS) primarily to identify ILs and their classifications.[1] The standard method does not examine the chemical attributes for brand identification. To achieve brand-level discrimination, additional analysis with statistical methods may be necessary to interpret complex GC/MS data.[2-4] Deep Learning (DL) employs multi-layered neural networks to automatically learn hierarchical features from labeled data, allowing for accurate classification of unseen data. Convolutional Neural Networks (CNNs) within DL have transformed the ability to recognize visual patterns, achieving highly accurate image classification in various applications.[5-7] This study aimed to develop a DL workflow to discriminate the brands of IL residues in fire debris samples. It is hypothesized that DL models trained on neat ILs could still learn to ignore irrelevant noise and focus on consistent features in GC/MS data, even when IL residues were chemically altered by fire and matrix interferences were present.

To prepare the training and testing dataset, 87-grade gasoline from Brands C, K, and Nylon carpet were purchased from local gas stations and a home improvement store in Houston, TX. A total of 198 samples, including neat gasoline diluted to various levels and simulated fire debris samples, were created and analyzed using Heated Headspace Solid Phase Microextraction combined with GC/MS (HHS-SPME-GC/MS). All GC/MS data were organized into training, verification, and assessment datasets. Pseudo-color heatmaps were produced from the raw GC/MS data to display selected mass-to-charge ratio (*m/z*) spectra at different retention times. These heatmaps were input into a DL model designed initially to classify images into 1,000 categories, which was fine-tuned to distinguish between Brand C and Brand K samples.

Experimental results showed that the DL model achieved 100% validation accuracy after training on the labeled dataset. To confirm these findings, unseen neat gasoline samples were tested, with the model reaching overall accuracy, sensitivity (Brand C class), and specificity (Brand K class) at 100±0% for samples with the lowest concentration of 0.39 µg per 20-mL HS vial and higher. To assess the model's ability to generalize degraded and matrix-interfered samples, simulated fire debris samples outside the training distribution were used. The model achieved 91.2±1.1%, 100±0%, and 82.4±2.0% for overall accuracy, sensitivity (Brand C class), and specificity (Brand K class), respectively, for samples with the lowest concentration of 6.25 µg per 20-mL HS vial and higher.

In conclusion, the development of the proposed DL workflow did not rely on extensive training data. It demonstrated robustness against chemical degradation and matrix interferences in post-fire ILs. Additionally, the approach facilitated automatic data interpretation, leading to consistent and reproducible results across different investigators. Combining DL with existing forensic techniques holds great promise for aiding source attribution of evidence and generating investigative leads.

B125 The Rapid Classification of Diesel and Gasoline by Raman Spectroscopy and Machine Learning in Support of Fire Investigations

Jung Tsai, BSc, Sam Houston State University, Huntsville, TX; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: The attendees will learn how to build a machine learning algorithm based on Principal Component Analysis (PCA) and Discriminant Function Analysis (DFA) using Raman scattering patterns of labeled gasoline and diesel samples. The attendees will also learn how to apply the algorithm to real-world forensic evidence in support of fire and criminal investigations.

Impact Statement: Raman spectroscopy is widely used in forensic science, especially for rapid detection and identification. This study demonstrates the potential of integrating Raman spectroscopy with machine learning to reliably distinguish between gasoline and diesel. The application of PCA and DFA offers a promising approach to address a persistent challenge in the rapid classification of Ignitable Liquids (ILs) in fire investigations.

Abstract Text: Recently, arson cases in Taiwan have frequently involved the use of ILs such as gasoline and diesel. These criminal tools can be directly obtained from gas stations with little or no modification. Traditionally, ILs are analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) to determine the category based on the American Society for Testing and Materials (ASTM) E1618.[1] However, rapid identification of diesel and the brand or type of gasoline is crucial in support of fire investigations. This task cannot be achieved by traditional GC/MS methods. The integration of machine learning and Raman spectroscopy is emerging as a revolutionary approach and has been shown promise in forensic classification tasks.[2] The combination of PCA and DFA with minimal training data and manual analysis can create an Artificial Intelligence (AI) -based workflow to distinguish ILs collected from crime scenes. Such an AI-based workflow has been regarded as a forensic application for any targeted identification tasks.[3]

In this work, regular, medium, and premium gasoline and diesel (a total of eight categories) from two major Taiwanese gas brands were collected and analyzed using micro-Raman spectroscopy with a 785 nm laser, covering a spectral range from 600 to 1800 cm^{-1}. Each sample was measured eight times, with an acquisition time of 3 seconds and 3 accumulations per measurement, resulting in a total of 64 Raman spectra. Subsequently, the spectra were normalized and PCA was performed. The results showed that the first two principal components accounted for 98.1% of the total variance. DFA was applied to classify the Raman spectra of eight oil types. The trained classifier achieved 100% accuracy (64/64) on the training dataset. Further validation of the trained classifier was conducted using a new dataset. It was found that diesel from different brands could not be identified, achieving only 50% accuracy (8/16). As for gasoline, the trained classifier successfully distinguished different brands of regular, medium, and premium gasoline with 91.6% accuracy (44/48). The trained classifier was also applied to at least 20 liquid evidence samples from real cases. The AI model successfully classified the evidence into one of the eight predefined categories in ten of the cases.

In conclusion, Raman spectroscopy combined with PCA and DFA offers a promising workflow for IL classification, even with limited training data. This study demonstrates how to deploy an AI model for gasoline and diesel in real case scenarios to facilitate investigation, providing investigative leads, such as narrowing down the locations for the retrieval of surveillance footage. As Raman spectroscopy becomes increasingly popular in practical applications, AI tools can enable the Raman technique to serve as a rapid evidence classifier in forensic intelligence.

B126 TNT Explosive Residue Detection: An Investigation of Swabbing Substrates and Solvents Across Witness Materials Using GC/MS

Krystal VanHorn, BS, Sam Houston State University, Germansville, PA; Nicholas Jernigan, MS, Sam Houston State University, Cypress, TX; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX; Jared Estevanes, PhD, Microtrace LLC, Elgin, IL*

Learning Objectives: After attending this presentation, attendees will obtain an understanding of the factors influencing the efficiency of 2,4,6-Trinitrotoluene (TNT) explosive residue recovery from different witness materials using various swab types and solvents using Gas Chromatography/Mass Spectrometry (GC/MS).

Impact Statement: This presentation will impact the forensic science community by demonstrating the most effective swab and solvent combinations for recovering TNT explosive residues from witness materials commonly encountered at crime scenes. The findings of this study will offer forensic practitioners an effective and practical sampling approach for optimized recovery and detection of TNT.

Abstract Text: Casework involving explosives continues to pose significant and evolving challenges for forensic practitioners around the world. In addition to the increased prevalence of Improvised Explosive Devices (IEDs), law enforcement agencies now progressively encounter civilians in possession of military-grade discarded ordinances, such as TNT, from war zones. Despite extensive research over the past decade, significant gaps remain in the field of sampling of explosive traces. Many studies focus on the analysis of intact explosives and materials spiked with the explosive analyte of interest, leaving research on sampling methodologies for the recovery and detection of authentic post-blast explosives residues relatively limited. This study aims to assess the effectiveness of several swab types and solvent combinations for detecting TNT explosive residues on various witness materials commonly found in explosive casework using GC/MS.

With the assistance of the Montgomery County Fire Marshal's Office (MCFMO), four simulated IEDs using TNT as the main charge were constructed and detonated in open-air field experiments. The explosive was placed into polypropylene toolboxes along with wooden paint sticks made of pine wood, squares of 100% cotton fabric, and strips of PVC electrical tape, which were employed as witness materials for sampling explosive residues. Following the explosion, the four materials were sampled with a dry cotton swab, a dry cotton ball, and cotton swabs solvated with methanol, acetone, and 1:1 methanol:deionized water. The swabs and cotton ball were extracted into a solution of acetone and Diphenhydramine (DPH), which was used as the internal standard. These extracts were passed through a syringe filter into a GC/MS vial. The peak areas from each replicate on the Total Ion Chromatogram (TICs) of the swab extracts were averaged and compared between the various swab types and witness materials.

Comparison of the witness materials demonstrated that the plastic substrate enabled the highest recovery rate across all swab types whereas fabric produced the lowest rate of recovery. Although fabric exhibited the lowest rate of recovery, it yielded the greatest TNT recovery when sampled with a cotton ball in contrast to the solvated swabs, which demonstrated minimal analyte recovery. A similar trend was observed with the wood substrate, where the cotton ball recovered higher amounts of TNT than the solvated swab, likely due to the materials' porous nature. In contrast, TNT recovery from the electrical tape was highly variable and was found to depend on the efficiency of the explosion, resulting in inconsistent findings across the four detonations. Among the swab types, the cotton ball exhibited higher average TNT recovery across the various witness materials examined. The results indicated that the rigidity and porosity of the witness material play a significant role in the ability to recover TNT residues.

This study demonstrates the importance of using authentic post-blast scenarios to determine the most suitable witness materials and swabbing techniques and to establish an effective workflow for TNT residue analysis. These findings will assist investigators in selecting optimal sampling methods based on the types of materials recovered at explosion scenes involving organic secondary high explosives such as TNT.

B127 Two Techniques, One Goal: An Analysis of Intact Explosives Using Confocal Raman Microscopy and Direct Analysis in Real Time-High Resolution Mass Spectrometry (DART-HRMS)

Shannon Keyser, BS, Sam Houston State University, Huntsville, TX; Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX; Jared Estevanes, PhD, Microtrace LLC, Elgin, IL*

Learning Objectives: After attending this presentation, attendees will gain an understanding of the advantages and limitations of using an integrated confocal Raman microscopy and DART-HRMS approach for identifying organic and inorganic components used in the fabrication of Homemade Explosives (HMEs).

Impact Statement: This presentation will impact the forensic science community by demonstrating a rapid and reliable workflow and methodology that require minimal sample preparation by combining confocal Raman microscopy and DART-HRMS for the analysis of intact explosives.

Abstract Text: When investigating an explosion, rapidly identifying the explosive compound is critical for producing investigative leads. HMEs, constructed using common household materials, are particularly challenging to classify and identify. These mixtures often contain organic and inorganic formulations, requiring multiple techniques for identification. Currently, Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) are commonly used for identifying explosives. However, these methods require extensive sample preparation, are time consuming, and destructive. This study explores the combined application of two rapid, non-destructive techniques, confocal Raman microscopy and DART-HRMS, to accurately and reliably identify intact explosives.

This study examined analytical standards and authentic samples representing three types of explosives: high explosives, inorganic oxidizers, and smokeless powder components. High explosive and inorganic oxidizer standards were dissolved and diluted before DART-HRMS analysis. Smokeless powders were ground, and their organic components extracted using ethyl acetate. For Raman microscopy, samples were prepared on a steel slide by placing a pinhead-sized amount of solid material or drying a 10 µL aliquot of liquid sample. Raman spectra were collected using a 785 nm laser for high explosives and inorganic oxidizers and a 532 nm laser for smokeless powders. For DART-HRMS, 5 µL of each standard solution was pipetted onto a QuickStrip and introduced to the instrument.

High explosives were detected using DART-HRMS in negative ionization mode facilitated by the high volatility of 2,4,6-Trinitrotoluene (TNT) and Pentaerythritol Tetranitrate (PETN). Although these compounds were also successfully identified using Raman microscopy, a key challenge was selecting sampling locations. This required the solvent to dry before examining remaining residue to determine an optimal location. Inorganic oxidizers were more readily identified using Raman microscopy than DART-RHMS. Nevertheless, DART-HRMS successfully detected ammonium nitrate and ammonium perchlorate using a 50:50 methanol:deionized water solvent. Characteristic ions for ammonium nitrate were observed at nominal *m/z* 98, *m/z* 178, *m/z* 258, *m/z* 338, *m/z* 418, and *m/z* 498, while a single characteristic ion at *m/z* 135 was identified for ammonium perchlorate. While the most prominent features in the Raman spectra correspond to anion stretching vibrations, lattice modes in the 100-250 cm^{-1} range enhanced discrimination between salts based on their cations. Smokeless powders were more easily differentiated using DART-HRMS than Raman microscopy. Using DART-HRMS, dimer species were detected for Ethyl Centralite (EC) and Methyl Centralite (MC) at *m/z* 537.3222 and *m/z* 481.2595 respectively. DART-HRMS also enabled the identification of EC and Diphenylamine (DPA) in authentic smokeless powder samples, along with nitroglycerin in negative ionization mode.

A proposed workflow was developed to assist analysts in identifying intact explosives, with initial analysis conducted using Raman microscopy. If an inorganic oxidizer without ammonia is detected, an alternative technique should be used for orthogonal confirmation. However, if a high explosive, smokeless powder, or ammonia-based oxidizer is identified, the sample should undergo solvent extraction for DART-HRMS analysis and orthogonal identification. This study demonstrates that combining Raman microscopy and DART-HRMS offers analysts a rapid and reliable method for screening a wide range of explosive compounds, including organic and inorganic components.

B128 Using Maggots as Passive Samplers for Explosive Odor Volatiles in Soil-Buried Scenarios

Laney Kimble, BS, Texas Tech University, Lubbock, TX; Joshua Smith, PhD, Texas Tech University, Lubbock, TX; Paola Tiedemann, PhD, Texas Tech University, Lubbock, TX*

Learning Objectives: After attending this presentation, attendees will gain a clearer understanding of how maggots can function as biosensors for detecting key odor volatiles emitted from buried plastic explosives.

Impact Statement: This presentation will impact the forensic science community by providing a proof-of-concept study that can potentially lead to a new method of detection for buried contraband and, in turn, offer a safer and cost-effective alternative for buried explosive detection in operational settings.

Abstract Text: Dating back to World War II, landmines have been utilized primarily by military forces as a defense tactic against opposing forces. They can be defined as concealed explosive devices constructed to cause injury, kill, or disable targets. A commonly encountered landmine is a blast mine, defined as a shallow burial and consisting of a trigger mechanism with an activation weight of as little as five pounds. To date, a key detection tool for this security threat has been metal detectors, but these have become less useful as developing landmines are reducing metal componentry and increasing the use of plastic materials. To circumvent this issue, biological detectors (biosensors) such as Explosive Detection Canines (EDCs) can assist in locating these mines. However, due to the extremely low trigger weight of these mines, EDCs are also at risk of becoming casualties.

Alternative biological detection systems, particularly insects, have gained interest for their sensitivity to Volatile Organic Compounds (VOCs). Insects such as honeybees, parasitic wasps, and locusts have been studied for their olfactory-based detection capabilities; however, maggots (fly larvae) remain largely unexplored in this context. Existing literature primarily focuses on maggots in forensic entomotoxicology, demonstrating their capacity to accumulate a wide range of chemicals from decomposing tissue, including drugs, toxins, and gun-related metals. Despite their proven bioaccumulation ability, no studies to date have evaluated their response to explosive-related volatiles such as those emitted by buried plastic explosives. This presentation explores the novel potential of maggots as biosensors for detecting key odor volatiles associated with buried plastic explosives, offering a low-cost, low-risk, and scalable alternative for future biological detection platforms.

Composition C4 (C4) was buried at a specified depth within three different soil types. Solid Phase Microextraction-Gas Chromatography/Mass Spectrometry (SPME-GC/MS) was then used to monitor odor dissipation of target explosive VOCs within the soil. Following, *Phormia regina* (Diptera: Calliphoridae) maggots were released and allowed to burrow within the soil for varying amounts of time. After the allotted time was complete, the maggots were collected, and their emanating odor profiles were analyzed vias SPME-GC/MS. The instrumental peak area responses from the individual maggots were compared to the peak area responses taken at baseline, when the explosive material was first buried. This comparison served as a percent recovery from the impregnated soil matrix to monitor the maggot's ability to retain explosive VOCs and serve as a biological substrate for explosive odor detection.

Evaluating the effectiveness of maggots in absorbing target VOCs is a critical step toward validating their use as living biosensors for explosive materials—and potentially other forms of contraband. By harnessing their natural chemical uptake abilities, this innovative approach could enhance detection capabilities for concealed threats such as landmines. Ultimately, incorporating maggot-based biosensors into detection protocols may not only improve accuracy and coverage in hazardous environments but also contribute to reducing casualties caused by hidden explosives.

B129 Augmenting Dogs and Sensors for Improved Detection of Explosives and Drugs

Stephen Isbel, MS, Global Forensic and Justice Center and Department of Chemistry and Biochemistry, Florida International University, Miami, FL; Patrick Roman, PhD, Global Forensic and Justice Center and Department of Mechanical and Materials Engineering, Florida International University, Miami, Florida, Miami, FL; Kenneth G. Furton, PhD, Florida International University, Miami, FL; Abuzar Kabir, PhD, Global Forensic and Justice Center and Department of Chemistry and Biochemistry, Florida International University, Miami, FL; Kelvin Frank, PhD, Global Forensic and Justice Center and Department of Chemistry and Biochemistry, Florida International University, Miami, FL; Michaela Clarke, MS, Global Forensic and Justice Center and Department of Chemistry and Biochemistry, Florida International University, Miami, FL*

Learning Objectives: Dogs and sensors are complementary with each having advantages over the other. While they are often viewed as competitive, in fact they often can be complementary, working in tandem. This study demonstrates the advantages of combining dogs and sensors for explosives and drug detection. While dogs generally alert to the odor of the target material, rather than the material itself , they do show a recognizable change in behavior when they detect the odor of a hazardous substance. At this point, standoff detection of the localized area can be achieved using long-range sensors for confirmation of the type of explosive material or illicit drugs.

Impact Statement: By studying various scenarios and locations using canines, quadruped robot-mounted long-range sensors, and hand-held long-range sensors, the optimum conditions can be determined. These optimized protocols can then be used in real-world scenarios to achieve the most efficient approach to a dangerous scenario. In addition, minimizing human interaction in the danger zone leads to a safer work environment for law enforcement and bomb squad personnel.

Abstract Text: This project, funded by the National Science Foundation's Industry-University Cooperative Research Center (NSF IUCRC) Center for Advanced Research in Forensic Science with the supports of the National Institute of Justice and Industry Partners identified the optimal combination of dog and sensor to be used as quickly and accurately as possible in a variety of operational settings focusing on explosives detection with drug detection to be completed in the next step. Explosives were handled and hid in packaging and placed in operational settings and dogs and sensors were tested to determine the individual accuracy and precision of each approach. This was followed by a combined approach to determine the improvement in the layered detection strategy. Working with certified law enforcement detector dog teams, the targets for testing were explosives.

Seven venues and 19 scenarios were tested. The venues were as follows: stadium, vehicle checkpoint, parking garage, student classroom, student lobby, office space, and seaport. Three types of detection were utilized for comparison to determine the most efficient response given the scenario: canine, handheld long-range sensor, and quadruped robot mounted with a long-range sensor.

This study has shown that chemical detection through coordinated canine alert training aids can be used as a localized guide for long range stand-off detection sensors. This can have a paradigm shift in how drugs and explosives are detected by demonstrating the relative advantages of dogs and sensors and the multiplicative advantage of leveraging these two orthogonal detectors to maximize the accurate detection of target materials in the minimum amount of time.

The experimental results show that canine alerts can be followed up with long-range sensors to accurately detect hazardous substances in a wide range of scenarios. In addition, these follow-up detections were quickly achieved due to the canine alert within the area of interest, allowing for a more efficient and safer response to a hazardous substance alert. It is apparent that hand-held, long-range sensor technology has advanced enough to efficiently and rapidly augment the detection canine throughout the various venues tested. It also demonstrated that dog and sensor combinations are safer and more effective when used together rather than individually.[1-12]

B130 Gelatin-Based Hydrogels as a Novel Medium for the Efficient Recovery of Organic Explosives from Post-Blast Residues: A Forensic Perspective

Khalid Sajjad Feras, MPhil, Trace Chemistry Department, Forensic Science Laboratory, Naif Arab University For Security Sciences, Riyadh, Ar Riyad, Saudi Arabia; Khaled Masoud, PhD, Naif Arab University for Security Sciences, Riyadh, Ar Riyad, Saudi Arabia; Syed Mujeebudin, MSc, Naif Arab University for Security Sciences, Riyadh, Ar Riyad, Saudi Arabia*

Learning Objectives: This study aims to investigate Gelatin-based Hydrogels (GHs) as a novel biocompatible medium to enhance the efficient collection of post-blast residues across a range of surfaces.

Impact Statement: GHs significantly enhance recovery rates of organic explosives from post-blast residues in comparison to the previously reported swabbing techniques by improving forensic analysis and potential applications in environmental monitoring and security.

Background: Forensic investigations require post-blast residue analysis to detect organic explosives like Trinitrotoluene (TNT), Pentaerythritol Tetranitrate (PETN), and 2-Nitrotoluene (2-NT). Traditional collection methods, such as cotton swabbing and solvent washing, only recover 50–70% of residues and are prone to contamination, particularly on porous surfaces. As a result, an environmentally friendly and efficient residue recovery medium is needed.[1]

Objective: This study aims to investigate GHs as a novel biocompatible medium to enhance the efficient collection of post-blast residues across a range of surfaces.[2]

Methods: The study evaluated GHs' ability to recover TNT, PETN, and 2-NT from ten different surfaces that were spiked with explosive solutions to replicate post-blast conditions.[1] For statistical validation, Analysis of Variance (ANOVA) ($p < 0.05$) was employed, and Gas Chromatography/Mass Spectrometry (GC/MS) triplicate experiments were conducted for reliability and qualitative identification.

Results: The results showed that recovery rates (mean ± 5% SD) on non-porous surfaces varied between 80 and 95%. GC/MS analysis confirmed distinct m/z peaks for each explosive: TNT (210, 193, 180), PETN (240, 194, 149), and 2-NT (137, 120, 91), with detection limits of 0.1–0.5 µg/mL and signal-to-noise ratios exceeding 3:1. These findings showed a high level of sensitivity.[4,5]

Conclusion: GHs are a cost-effective and field-applicable alternative to traditional residue collection methods that significantly improve residue recovery and analytical reliability. This technique enhances forensic capabilities in post-blast investigations and may find application in environmental monitoring and homeland security. Future research should validate GHs in real-world scenarios and expand their use to other explosives to improve their forensic utility.

B131 Beyond the Surface of Architectural Paint: A Comparative Analysis Using DART-MS and Spectroscopic Techniques

Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX; John Laetsch, III, MS, Sam Houston State University, Spring, TX; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX; Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; Morgan N. Carpenter, BS, Sam Houston State University, Wylie, TX*

Learning Objectives: After attending this presentation, attendees will gain an understanding of the strengths and limitations of Direct Analysis in Real Time-Mass Spectrometry (DART-MS) for detecting components in architectural paint, particularly in comparison with spectroscopic techniques commonly employed in paint analysis.

Impact Statement: This presentation will impact the forensic science community by demonstrating the capabilities of DART-MS for identifying architectural base paints and their mixtures, as compared to Fourier Transform Infrared (FTIR) spectroscopy and Scanning Electron Microscopy/Energy Dispersive X-ray Spectroscopy (SEM/EDS). The findings offer practical implications for expanding current analytical workflows in the forensic examination of paint by incorporating DART-MS as a complementary technique.

Abstract Text: Architectural paint is a commonly encountered form of transferred trace material in forensic investigations, particularly in break-in cases. While there is no single, standardized workflow for the analysis of this substance, the recommended approach follows a progression from non-destructive to increasingly destructive techniques. These include microscopical examinations, followed by Fourier Transform Infrared (FTIR) spectroscopy and, when necessary, complementary techniques such as SEM/EDS, Pyrolysis-Gas Chromatography/Mass Spectrometry (Py-GC/MS), or Raman spectroscopy. Given the growing interest in the forensic use of Direct Analysis In Real Time-Mass Spectrometry (DART-MS) for the analysis of trace evidence, this study aimed to evaluate its capabilities in comparison with FTIR and SEM/EDS and to explore its potential role in a paint analysis workflow.

Forty-five binary mixtures were created in ratios of 90:10, 75:25, 50:50, 25:75, and 10:90 from five base color paints, representing the white, black, blue, red, and yellow color families, in known proportions to produce a large array of possible color shades. The base colors and mixtures were applied to individual glass microscope slides and allowed to air dry. Thin shavings from the dried paint were analyzed by DART-MS in both positive and negative ionization modes with a gas heater temperature of 350°C and 500°C using a direct sampling method. For micro-FTIR analysis, the shavings were rolled flat using a roller knife before being transferred onto a polished sodium chloride pellet. Additionally, a subset of the shavings, including the five base color paints and mixed paints containing the combination of blue and white base paints, were analyzed using SEM/EDS to examine the inorganic components of the paints.

DART-MS successfully detected a range of organic compounds commonly present in architectural paint. The identified compounds included plasticizers, additives, and solvents such as tributyl citrate, polyethylene glycol, dioctyl maleate, and tert-butyldiethanolamine, which were not identified using FTIR spectroscopy or SEM/EDS. Additionally, DART-MS demonstrated the capability to detect a characteristic ion at a nominal m/z 162, associated with the black base paint, in mixtures containing concentrations above 10% at both 350°C and 500°C. This distinguishing feature was not observed using either FTIR or SEM/EDS. As anticipated, FTIR spectroscopy proved effective in identifying both organic and inorganic components within the base paints and their mixtures, including binders, pigments, and extenders. Meanwhile SEM/EDS demonstrated enhanced sensitivity for trace-level inorganic compounds, also informative of pigments and extenders.

This study demonstrates the benefits and limitations of using DART-MS for analyzing architectural paint mixtures and provides a comparison with established spectroscopic techniques. Since all three techniques provided different chemical information about the architectural paint samples, the results not only showed their complementary nature but also highlighted the value of DART-MS in a forensic paint analysis workflow, particularly in detecting organic components and improving mixture differentiation.

B132 Developing a Scale to Categorize the Sheddability of Fibers From Fabrics

Flavia Bucci Casari degli Atti di Sassoferrato, MS, University of New Haven, West Haven, CT; Ted R. Schwartz, MS, University of New Haven, West Haven, CT*

Learning Objectives: Attendees will learn about the development of a technique designed to assess how readily a garment sheds its fibers. The developed technique was tested on numerous fabrics of various fiber types, and a sheddability scale was established. The technique is relatively inexpensive and easy to perform. From this presentation, the attendees will learn the importance of communicating and assessing the results of a fiber comparison.

Impact Statement: If crime laboratories were to implement this technique, they would be able to better communicate how easily a textile material sheds its fibers. This is important in interpreting the meaning of a fiber transfer in a forensic case.

Abstract Text: The purpose of this research project was to examine the sheddability of fibers and to create a scale that can be used by crime laboratories to establish how easily fibers of various garments may be transferred. Locard's Exchange Principle states that material from two different surfaces can be exchanged through direct contact with each other. The occurrence of transferred fibers can provide valuable evidence in criminal cases. At present, there is no standardized method for conveying the ease with which fibers can be transferred from a particular garment to other surfaces or items. This lack of communication poses challenges for trace evidence examiners who need to assess the transferred fibers in forensic identifications. The objective of this paper is to propose a comprehensive procedure and a detailed scale that experts can utilize to effectively evaluate and communicate this sheddability factor. The aim of this project is to enhance the accuracy of fiber transfer assessments, ultimately contributing to more reliable evidence interpretation.

For this project, a total of 160 clothing items were tested. The clothing was composed of different fiber types, including acrylic, cotton, polyester and others. A two-inch by two-inch piece of Scotch packing tape was placed on top of the item. A 1kg weight was placed on top of the tape for 30 seconds. Afterward, the tape was lifted and stuck onto a piece of clear transparency film. It was then examined under a stereo microscope to count the transferred fibers. This procedure was designed to be simple, inexpensive, and reproducible, so that it could easily be implemented in a forensic laboratory.

A sheddability scale ranging from 0 to 5 was developed based on the quantity of fibers retrieved from each item. The number of transferred fibers ranged from 0 (a nylon garment) to 248 (a cotton/spandex blend). The average number of fibers transferred was 77. Based on this data, the scale was set up in the following manner:

0: 0 Fibers (No shedding)
1: 1-10 Fibers (Very low shedding)
2: 11-30 Fibers (Low shedding)
3: 31-80 Fibers (Moderate shedding)
4: 81-140 Fibers (High shedding)
5: 141+ Fibers (Very high shedding)

This method is cost-effective, utilizes readily available materials, and requires minimal time to perform. It is proposed that forensic laboratories consider adopting a standardized technique such as this. The scale offers a universal framework for assessing and communicating the degrees to which fibers are shed from textile materials, enhancing consistency and clarity in forensic reporting. This research aligns with the 2026 AAFS theme, "Back to Basics: The Fundamentals of Forensic Science," by reinforcing the use of accessible and practical tools to enhance consistency in forensic fiber analysis and trace evidence interpretation.

B133 Evaluating the Reproducibility and Interpretive Value of Micro-Spectrophotometry in the Forensic Differentiation of Blue Cotton and Polyester Fibers

Britney Hitt, MSc, University of Central Florida, Orlando, FL; Deborah K. Moi, BSc, University of Central Florida, Orlando, FL; Larry Tang, PhD, University of Central Florida, Orlando, FL; Slun Booppasiri, MS, University of Central Florida, Orlando, FL; Andres D. Campiglia, PhD, UCF-Chemistry, Orlando, FL; Maria Aldaba, University of Central Florida, Orlando, FL*

Learning Objectives: Attendees will gain insights into the reproducibility and interpretive value of Micro-Spectrophotometry (MSP) -derived spectra in forensic comparisons, with a focus on two commonly encountered fiber–color combinations in casework: blue cotton and blue polyester. To account for manufacturing and dyeing variability, fiber samples were sourced from multiple commercial garments.

Impact Statement: The findings underscore the potential of MSP to reliably differentiate fibers based on spectral characteristics, reinforcing its value as a non-destructive and highly informative technique in forensic fiber analysis.

Abstract Text: This presentation examines the use of non-destructive methodologies in forensic fiber analysis, highlighting their essential role in preserving the integrity of evidence for legal proceedings. The ability to differentiate visually similar fibers or associate a questioned sample with a known source—without altering or consuming the material—is a cornerstone of forensic science.

Among the available techniques, MSP emerges as a particularly powerful tool. MSP facilitates the acquisition of both absorption and fluorescence spectra from individual fibers using transmission or reflectance modes. This approach yields detailed spectral data related to fiber color and chemical composition while maintaining the sample's physical integrity.

For each fiber type, absorption spectra were collected from three regions on 30 individual fibers, resulting in a total of 90 spectra per type. Fluorescence spectra were obtained using filter cubes with nominal excitation wavelengths of 365 nm, 420 nm, and 546 nm. Three regions were analyzed per fiber, yielding 270 fluorescence spectra per fiber type. The presentation also addresses potential photobleaching effects during spectral acquisition and underscores the importance of selecting appropriate microscope lenses for single-fiber fluorescence analysis.

Finally, the presentation provides a summary of optimal wavelength ranges and irradiation times that minimize—or eliminate—photobleaching, specifically for the forensic examination of cotton blue and polyester blue fibers.[1-3]

B134 A Multi-Analytical Characterization and Discrimination of Electrical Tapes Using GC/MS, FTIR, and Evaluation of Physical and Optical Properties

Rayven Cobb, BS, Department of Forensic Science, Virginia Commonwealth University, Henrico, VA*

Learning Objectives: Attendees will learn how to apply a multi-instrumental workflow for analyzing electrical tape samples in forensic casework. They will also gain an understanding of how chemical and microscopic techniques can complement each other in evaluating trace materials.

Impact Statement: This research enhances the forensic discrimination of pressure-sensitive tapes by integrating chemical, physical, and optical analyses. It contributes to the development of standardized methodologies that increase the reliability of tape comparisons in forensic investigations.

Abstract Text: Electrical tape is frequently encountered in forensic investigations involving violent crimes, drug packaging, and improvised explosive devices. Its layered composition, including a polymeric backing, adhesive, plasticizers, and additives, provides multiple points of comparison for forensic analysis.[1-3] This study aims to differentiate electrical tapes from 14 different manufacturers using a multi-analytical approach focused on physical, optical, and chemical properties. Twenty-eight tape samples were evaluated through stereomicroscopy, polarized light microscopy, and fluorescence microscopy to document morphological and optical characteristics. Fourier Transform Infrared Spectroscopy with Attenuated Total Reflectance (FTIR/ATR) and Gas Chromatography/Mass Spectrometry (GC/MS) were used to identify polymers, functional groups, and organic components, including plasticizers and additives. Solvent extraction and separation techniques prepared distinct tape layers for analysis.

Results showed that certain types of electrical tape had multiple colored particulates embedded in the adhesive layer, visible under polarized light. These particles appeared in greater concentration after the adhesive was treated with hexane for removal, suggesting they may be inorganic fillers or manufacturing residues. The presence, color, and concentration of these particles may serve as potential markers for distinguishing between tape sources. FTIR profiling indicated that compositional differences existed in both the adhesive layer and the backing layer, likely driven by the presence and/or abundance of inorganic binders in some tape brands. Similarly, differences detected with GC/MS profiling can be combined with microscopic observations and FTIR spectra to increase discrimination among manufacturers/sources of electrical tape.

B135 On the Characterization and Differentiation of Clearcoats in Automotive Paint Using UV-Visible Microspectrophotometry, FTIR Spectroscopy, and Raman Spectroscopy

Swathi Murali, Sam Houston State University, Huntsville, TX; Morgan N. Carpenter, BS, Sam Houston State University, Wylie, TX; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will understand the contribution in terms of complementarities and redundancy of common spectroscopic techniques used in the forensic examination of paint, specifically for the analysis of clearcoats.

Impact Statement: This presentation will impact the forensic science community, especially trace evidence examiners, by providing essential information for practitioners to develop an effective analytical scheme with high discriminating capabilities for characterizing and comparing automotive paint clearcoats.

Abstract Text: Automotive paints are examined in forensic laboratories mainly in relation to hit-and-run accidents and traffic collisions. The forensic examination of paint begins with macroscopical and microscopical examinations, followed by various instrumental analysis methods. Typical paint systems are multilayered and primarily consist of a clearcoat, basecoat, primer, and primer surfacer. While a vast body of literature exists on the analysis of the colored basecoat layers, research on clearcoats has been sporadic. Clearcoats form the topmost, protective layer of an automotive paint finish system and, hence, are prone to transfer during a collision, thereby establishing their forensic interest. This layer is primarily composed of a binder or a resin interspersed with additives such as UV Absorbers (UVA). While the chemical composition of the binder is typically recorded using Fourier Transform Infrared (FTIR), the results showed that this component was also preferably detected using Raman spectroscopy. However, UVAs absorb energy in the 240-400 nm wavelength range of the electromagnetic spectrum and consequently can be studied using UV-Visible Microspectrophotometry (UV-Vis MSP).

The goal of this project was to develop an efficient, highly discriminating analytical scheme using UV-Vis MSP, Raman spectroscopy, and FTIR spectroscopy for the analysis of automotive paint clearcoats. Forty-nine automotive paint samples across various manufacturers, models, colors, and years were characterized using these three spectroscopic techniques. The acquired spectra were first qualitatively assessed to determine the chemical composition of clearcoats. Subsequently, the discriminating power of each analytical technique was calculated. Using UV-Vis MSP spectra, samples were assigned to 29 groups, resulting in a discriminating power of ~97%. In comparison, both FTIR and Raman spectroscopy could discriminate ~99% of the samples. Combining all three techniques yielded a high discriminating power of approximately 99.9%. However, similar levels of discrimination could also be achieved by using any two techniques—MSP + FTIR, MSP + Raman, or FTIR + Raman.

When developing an analytical scheme to examine automotive paint clearcoats, it is important for analysts to consider not only the discriminating power but also the complementarity of information provided by each technique. In this case, FTIR and Raman spectroscopy provided similar information about the binder(s) present in clearcoats, whereas UV-Vis MSP provided complementary information about the presence of UV absorbers.

B136 Thermal Alteration of Pollen Grains: Implications for Forensic Analysis

Jessica D. Valerio, Loyola University New Orleans, New Orleans, LA; Anna S. Duggar, PhD, Loyola University New Orleans, New Orleans, LA*

Learning Objectives: After attending this presentation, participants will have an improved understanding of changes in the structure and chemistry of pollen grains with exposure to different amounts of heat for different timespans. They will understand how characterization of these changes can potentially be harnessed to provide insights for forensic investigations.

Impact Statement: This research provides the forensic science community a greater understanding of the potential predictive correlations between physical and chemical changes in pollen grains and temperature/duration of heating. The findings presented have the potential to inform real-world thermal exposure scenarios.

Abstract Text: Pollen is a valuable type of particulate evidence characterized by its ubiquitous presence and high transferability. In addition, pollen populations can vary from one season to another and across geographies, depending on a locality's flora. These characteristics give pollen a role in forensic investigation, where the transferable particulate can help provide suspect identification, alibi corroboration, and geographic information relative to the reconstruction of the events of a crime. Forensic palynology, the analysis of pollen and spores for use in criminal investigations, is often used in the United Kingdom, but remains largely unused in United Staters courts.[1] The notable absence of forensic palynology in the American legal system is reportedly due to a combination of lack of experts, lack of training, lack of funding, and a resulting lack of confidence among law enforcement and court personnel that pollen evidence would be admissible without substantial investment in fundamental research.[2]

Previous studies have shown that heating pine pollen to temperatures up to 290°C over 24 hours can cause observable changes in size and color.[3] This study analyzes the effects of moderate heat exposure over briefer timespans. In particular, this investigation probes any proportional relationship between temperature and duration of exposure to heat and changes in pollen integrity and chemistry.

Pine and fennel pollens were heated at either 80 or 105ºC for either 30 or 120 minutes, resulting in four different heat/time combinations. After heating, the grains were analyzed via light microscopy, Scanning Electron Microscopy (SEM), and Fourier Transform Infrared/Attenuated Total Reflectance (FTIR/ATR) microscopy.

Visible damage was observed by both light microscopy and SEM, including cracking, shriveling, and even disintegration of the grains. Calculated area in the fennel pollen population displayed an initial decrease on heating, followed by a range rebound to include grains larger in area than those in the untreated pollen population. In pine pollen, heated populations were similarly seen to include noticeably larger grains. These results were consistent with previous research, where initial shriveling of the grains was attributed to loss of volatile components like carbohydrates and proteins, followed by thermal expansion.[4] Additionally, preliminary analysis of individual grains by micro-FTIR/ATR seemed to show a loss of intensity for characteristic peaks.

The work promises to identify trends that may guide forensic palynologists in understanding heat damage to pollen grains for forensic applications.

B137 DyeSPY: Establishing the First Forensic SERS Reference for Hair Dye Colorant Evidence

Aidan P. Holman, BSc, Texas A&M University, College Station, TX; Avery Maalouf, Texas A&M University, College Station, TX; Dmitry Kurouski, PhD, Texas A&M University, College Station, TX*

Learning Objectives: After attending this presentation, attendees will: understand the forensic and toxicological importance of a comprehensive hair dye database. Attendees will be able to explain why traditional hair dye analysis methods are limited and how a modern, chemically specific approach can improve forensic identification and toxicological evaluation; describe the construction and capabilities of the DyeSPY database. Attendees will learn how DyeSPY integrates Surface-Enhanced Raman Spectroscopy (SERS) with machine learning to detect trace dye components and predict original dye colors, filling critical gaps in current forensic dye databases; and recognize the operational workflow and analytical strengths of the DyeSPY system. Attendees will gain insight into how the DyeSPY pipeline processes spectral data, assigns colorant identities, and outputs color predictions, enabling reliable forensic comparison even with degraded or mixed samples.

Impact Statement: This research introduces a novel, objective, and chemically specific method for analyzing hair dyes (on hair), an often-overlooked form of trace evidence. The development of the DyeSPY database leverages SERS and machine learning, allowing for the identification of individual colorants, including couplers, at trace levels, and predicts the original appearance of dyed hair, even in degraded samples. Unlike traditional light microscopy or bulk spectroscopic methods, DyeSPY provides reproducible, component-level data that can support suspect and victim identification, timeline reconstruction through witness accounts of suspect hair color, and toxicological hazard assessment. By bridging the gap between physical evidence and digital interpretation, this approach modernizes forensic hair analysis and expands its evidentiary value in both investigative and courtroom settings.

Abstract Text: Hair dyeing is a prevalent practice worldwide[1] Given its widespread use and significance for personal identity, hair dye may have potential forensic applications in individual identification. Traditional forensic hair analysis relies on light microscopy to assess characteristics such as racial origin, treatment history, and dye presence. However, this method is highly subjective and often requires a follicular root, which stars to degrade after hair is shed.[2] Alternative spectral techniques, including high-performance thin-layer chromatography, X-ray fluorescence, and ultraviolet-visible spectroscopy, have been explored to enhance objectivity in dye analysis.[3] Despite their utility, these techniques primarily identify broad spectral characteristics rather than individual dye components. Infrared and Raman Spectroscopy (RS) offer improved chemical specificity due to extensive reference libraries but struggle to detect low-concentration colorants.[4] SERS addresses this limitation by utilizing plasmonic metal nanoparticles to amplify Raman signals, enabling the detection of trace dye components, even in degraded samples.[5] While existing forensic dye databases provide reference-based colorant identification, they do not incorporate couplers or suggest original colors a sample can create.[4] We developed DyeSPY, a first-of-its-kind platform that exploits the synergy between SERS and machine learning to identify hair dye colorants and their predicted colors. Such a database could significantly enhance forensic investigations, aiding in victim and suspect distillation, as well as detecting hazardous colorants for toxicological assessments.

B138 The Persistence of Soil Traces on Footwear: Interactions Between Organic Content and Contact Surface

Ashley Buchman, BS, Cedar Crest College, Andover, NJ; Jennifer Bonetti, PhD, Virginia Department of Forensic Science, Norfolk, VA; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA; Andra Lewis, PhD, Cedar Crest College, Allentown, PA*

Learning Objectives: Attendees will learn how soil organic content and type of walking surface influence the persistence of soil on footwear following a controlled walking activity. Through statistical comparisons and regression analysis, participants will gain insight into how substrate conditions, soil composition, and body weight affect the transfer and retention of soil as trace evidence. These findings could have substantial implications for the interpretation of soil traces in forensic investigations and may assist in the development of more robust evidentiary assessments.

Impact Statement: This presentation enhances the forensic community's understanding of particulate trace evidence by introducing a replicable framework for evaluating soil transfer and persistence. By integrating empirical data with forensic interpretation, the findings will improve the competency of examiners in reconstructing activity and movement pathways from soil evidence, directly strengthening case evaluations and courtroom testimony.

Abstract Text: Soil is a valuable form of trace evidence due to its widespread occurrence, compositional variability, and potential for associative transfer. However, its forensic utility depends on understanding the factors that affect transfer and persistence under real-world conditions. This study investigates how soil organic content and type of walking surface (pavement vs. grass) influence soil retention on footwear, which is listed as a research priority by the Organization of Scientific Area Committees (OSAC) Subcommittee on Trace Materials.[1]

Soils were collected from all 13 geological regions of New Jersey and categorized into low-, medium-, and high-organic groups using the loss-on-ignition method, with organic content ranging from 0.17% to 96.01%.[2] Soils were hydrated at fixed water-to-soil ratios, and 1.5g were applied to clean athletic footwear worn by 18 participants who walked 0.1 miles on both surfaces.[3] To minimize variability, all participants wore identical athletic footwear of the same brand and model; no other types of footwear were used. The percent of soil remaining post-walk was then measured to quantify persistence.

Statistical analysis revealed significant effects of soil type and walking surface on soil retention. One-way Analysis of Variances (ANOVAs) showed significant differences among soil types on both pavement ($F = 40.73$, $p < 0.001$) and grass ($F = 37.13$, $p < 0.001$), with medium-organic soils exhibiting the highest persistence on both surfaces. Two-way ANOVAs indicated that both soil type and participant weight significantly influenced retention ($p < 0.01$), with a small but significant interaction on grass ($p = 0.0395$). Regression models demonstrated a negative correlation between participant weight and soil persistence ($p < 0.05$), except for high-organic soils on grass, which uniquely exhibited a positive trend with increasing weight.

Findings show that pavement favors the retention of mineral-rich, low-organic soils, while grass supports higher retention of organic-rich soils, particularly in heavier participants. These results align with prior research demonstrating how substrate texture, soil composition, and biomechanical variables influence particulate transfer and persistence.[4-10]

Although this study was limited to a single type of athletic footwear, these findings attempt to advance forensic soil analysis by providing empirical support for the role of organic content and surface type in soil retention on footwear. The results should be interpreted within this context but, nonetheless, offer a practical framework for interpreting soil evidence and reconstructing movement history in forensic contexts[6,9,11]

B139 A Comparison and Characterization of Nitrocellulose, Gel, and Dip Powder Nail Products as Forensic Trace Evidence

Madison Lindung, MSFS, West Virginia University, Morgantown, WV; Mallory Higgins, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: During this presentation, attendees will be introduced to the foundational chemistry, manufacturing, and interpretation of modern nail polish products as relevant trace materials. Attendees will assess relevant features to classify nitrocellulose-based, Ultraviolet (UV) -curable gel, dip powder polishes, modifications of pre-prepared films, and artificial nails. The attendees will evaluate the presented data on the discrimination power of analytical methods and the rarity of physical and microscopic features for the interpretation of contemporary nail polishes.

Impact Statement: The findings in this research will highlight critical information for the forensic science community to classify, compare, and interpret contemporary nail products in contrast to other paint materials. The presentation will increase examiners' knowledge and understanding of modern nail polish products, lifespan, formulations, and potential use to provide leads in forensic investigations of violent crimes, such as homicides, kidnappings, and sexual assaults.

Abstract Text: Due to the fragility of nails and the use of hands as a first mechanism of defense, forensic investigators can find nail polish evidence at the scene of violent crimes such as homicides, assaults, or kidnappings. This study expands the knowledge base of forensic examinations of nail polishes by evaluating the chemical and physical properties of contemporary products. The presentation explores how this information aids in classifying nail polish types, comparing nail polishes with other commonly encountered paints, generating investigative leads, and interpreting comparative results.

The experimental design evaluates the discrimination power, microhomogeneity of products, and distinctive features from a dataset composed of 40 artificial and natural nail substrates, 23 modifications of pre-prepared films and press-on nails, and 164 polishes collected from three modern nail polish products (nitrocellulose, UV-curable gels, and dip powders) with 11 colors and 5 brands. The analytical workflow follows standard methods for paint analysis (American Society for Testing and Materials [ASTM] E1610) using: (1) macroscopical examination, (2) microscopical examination, (3) micro-solubility, (4) Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR), and (5) Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS).[1] With a final discrimination power of 99.99% across 13,366 possible pairwise comparisons and the 5 analytical techniques, this study showcases the rarity of features within nail polish product types microscopically and the distinct chemical properties of the main binders, extenders, colorants, and other additives found within modern nail polish chemistry. A mock case scenario can illustrate how forensic laboratories can use this information to examine, interpret, and disseminate their findings.

B140 Adhesive Tapes as Sorbent Supports: The Innovation, Challenges, and Potential of Activated Charcoal-Coated Tapes for Fire Debris Analysis

Grace Boyer, Eastern Kentucky University, O'Fallon, MO; Alyssa R. Eddington, BS, Eastern Kentucky University, Mount Washington, KY; Cynthia JK Tran, PhD, Eastern Kentucky University, Richmond, KY; Derek T. Collins, BS, Eastern Kentucky University, Lexington, KY*

Learning Objectives: Attendees will learn about a proposed approach to collecting ignitable liquid residues from fire debris using activated charcoal-coated tapes as an alternative to traditional activated charcoal strips or powders. This presentation will highlight practical considerations, comparative performance data, and implementation challenges associated with this lower-cost, customizable method.

Impact Statement: This research introduces groundwork toward an alternative adsorption package for passive headspace sampling in fire debris analysis. While this method is not yet optimized for routine casework, it introduces a fresh perspective on sample collection that may inspire further research, collaborative development, and refinement of low-cost alternatives for passive headspace sampling.

Abstract Text: Passive headspace concentration using activated charcoal strips or powder-filled "C-bags" is a well-established method for the recovery of ignitable liquids from fire debris.[1] This presentation explores a novel collection method: coating various types of adhesive tape with Activated Charcoal Powder (ACP) to create a device that offers the structure of a strip and the low cost of powder. The hypothesis driving this work was that activated charcoal-coated tapes could serve as a viable alternative for passive sampling, provided the material could retain adequate charcoal, allow effective analyte extraction, and exhibit minimal interference with subsequent Gas Chromatography/Mass Spectrometry (GC/MS) analysis.

To this end, multiple household and laboratory tapes were tested, including pressure-sensitive tapes manufactured for different personal and industrial uses. These were coated with ACP under controlled conditions and then evaluated for loading capacity and persistence of ACP on the tape. Results revealed significant variation in the amount of charcoal that different tape types could retain. Across the board, charcoal loading was below the threshold recommended in American Society for Testing and Materials (ASTM) E1412-19 when using powder in C-bags, raising questions about sampling efficiency[1].

Additionally, the solvent extraction of ignitable liquids from the charcoal-coated tapes was examined using three solvents recommended in ASTM E1618-19—carbon disulfide, diethyl ether, and pentane.[2] Some tapes contained extractable interferences, complicating chromatographic analysis. Interestingly, the tapes with the cleanest chromatograms (minimal interference) often had poor charcoal loading, presenting a trade-off between chemical cleanliness and sampling effectiveness.

This research offers a preliminary proof-of-concept for a potentially cost-effective and customizable sampling medium. Though technical challenges remain in optimizing charcoal retention and ensuring compatibility with extraction solvents, these findings may inform future revisions of fire debris analysis protocols or spur additional development of alternative collection substrates.

B142 Identifying Fiber Sources From Absorbance Spectral Data Using Statistics and Machine Learning

Slun Booppasiri, MS, University of Central Florida, Orlando, FL; Larry Tang, PhD*, University of Central Florida, Orlando, FL; Andres D. Campiglia, PhD, UCF-Chemistry, Orlando, FL; Britney Hitt, MSc, University of Central Florida, Orlando, FL; Deborah K. Moi, BSc, University of Central Florida, Orlando, FL; Maria Aldaba, University of Central Florida, Orlando, FL*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how we identify the wavelengths where polyester blue fibers from three manufacturers show differences using Analysis of Variance (ANOVA). We also use machine learning to classify polyester blue fibers among the three manufacturers.

Impact Statement: This presentation will impact the forensic science community by introducing ANOVA and machine learning methods to analyze polyester blue fibers. The methods could be applied to other sections that use absorbance spectral data.

Abstract Text: Literature reports on fiber prevalence in forensic casework consistently identify black/gray-cotton and non-denim blue-cotton as the most frequently encountered color–fiber combinations at crime scenes.[1-7] More recent studies from the National Center for Forensic Science (NCFS) and the West Virginia Forensic Science Initiative have statistically assessed the probability of encountering various fiber type-color pairings in transferable fiber populations.[6,7] The most prevalent combination was blue/purple-cotton, followed by black-cotton and white-cotton.

Fiber images, absorption spectra and fluorescence spectra were recorded from 30 fibers per fiber type. Single fibers were removed from 10 different regions of each cloth unit using tweezers. At least 1 fiber per area of clothing will be analyzed, totalizing a minimum of 10 fibers per piece of clothing. Three pieces of clothing per each fiber type were analyzed, resulting in a minimum total of 30 fibers per fiber type. Absorbance spectra were recoded from three different areas of single fibers, resulting in a total of 90 absorption spectra per fiber type. Fluorescence spectra were recorded with each filter cube from three different areas of single fibers, resulting in 270 fluorescence spectra per fiber type.

We did preliminary studies on polyester blue fibers to identify the wavelengths in which the three manufacturers differ. The Analysis of Variance (ANOVA) was applied to test if there is statistically significant difference among three manufacturers for each wavelength under each of the four spectra. ANOVA evaluates all three simultaneously to assess whether at least one manufacturer's fiber samples differ significantly in their average counts. The method works by partitioning the total variation in the data into two components: variation between manufacturers (how much each manufacturer's average measurement differs from the overall average) and variation within manufacturers (how much individual fiber samples vary within each manufacturer's group). The ratio of these two sources of variation is calculated as the F-statistic. A large F-value suggests that the differences among manufacturers are unlikely to be due to random chance. If the associated p-value is below a chosen threshold, we conclude that at least one manufacturer's fiber samples are statistically different in their average properties.

In addition, machine learning methods were used to classify polyester blue fibers from the three manufacturers. Firstly, the data was divided into a training set and a validating set. Since the number of wavelengths (variables) exceeded the number of samples, Principal Component Analysis (PCA) was applied to reduce the number of variables. We then trained seven machine learning models including logistic regression, Least Discriminant Analysis (LDA), Quadratic Discriminant Analysis (QDA), Support Vector Machine (SVM), Random Forest (RF), XGBoost, and Neural Network (NN) on the training set and compare performances of the methods by predicting the fiber manufacturers in the validating set.

B143 Exploring the Persistence and Transfer of Trace DNA Samples Recovered From Doorknobs in Burglary Simulations

James E. Seltzer, BS, Arcadia University, Philadelphia, PA; Mechthild Prinz, PhD, John Jay College of Criminal Justice, New York, NY; Georgina E. Meakin, PhD, UTS Centre for Forensic Science, Ultimo, New South Wales, Australia; Fabio Oldoni, PhD, Arcadia University, Glenside, PA*

Learning Objectives: After attending this presentation, attendees will have a deeper understanding of how variables of recovery time and contact time impact DNA transfer during a contact, specifically as it relates to mock burglary simulations.

Impact Statement: This presentation will impact the forensic science community by exploring the transfer, persistence, and recovery of DNA on doorknobs used in a mock burglary scenario. This presentation expands upon the current body of knowledge about detecting and recovering the DNA of an offender, specifically from a burglar.

Abstract Text: Trace DNA is often deposited on objects and surfaces at crime scenes due to direct and indirect transfer.[1] This DNA evidence has significant forensic potential for establishing a link between a crime scene and an offender. There is a significant body of literature exploring the forensic applications of DNA evidence, but there is little focus on DNA collection from burglary crime scenes. Additionally, an imbalance remains between evidentiary findings and the weight of propositions presented in court regarding DNA evidence, so it is necessary that this research continues to improve understanding.[2]

In this research, burglary simulations are performed using doorknobs as a substrate involved in DNA transfer. In each simulation, a mock homeowner touches the brass or stainless steel doorknob for 30 minutes spread across three days. This contact serves to form a background presence of DNA on the doorknob. Secondly, a mock offender touches the same doorknob for either one or three minutes, which serves to simulate a burglar entering a home. The doorknobs are then sampled using the double swab technique after a period of either one hour or three hours. These simulations allow focus on two variables as they relate to burglaries—the length of contact with the doorknob and the time period between the offender contact and the recovery of the DNA. These variables are referred to as contact time and recovery time, respectively.

Ten volunteer pairs will perform simulations as the mock homeowner and other simulations as the mock offender. Reference samples for each volunteer are collected from buccal swabs and extracted using Chelex resin. Samples will be collected from the doorknobs of burglary simulations using Puritan cotton swabs and the double swabbing technique. DNA is extracted from the samples using QIAamp DNA Investigator Kit and QIAshredder kit. Extracted samples are then quantified using Trio Quantification kit and QuantStudio 5 Real-Time PCR System. Quantified samples are then amplified using GlobalFiler Amplification Kit and ProFlex 96-well PCR. Amplified samples are then separated by capillary electrophoresis using SeqStudio Genetic Analyzer, and Short Tandem Repeat (STR) profiles are analyzed using GeneMapper ID-X software.

Preliminary results have been collected and analyzed from 17 samples out of over 60 trace samples. DNA quantification values from these samples have ranged between 0.004ng/µL and 0.106ng/µL. All samples analyzed using GeneMapper ID-X software have indicated the presence of mixed STR samples. Eleven of the 17 samples tested have produced a full STR profile, and 6 have produced a partial STR profile, which included the mock homeowner and mock offenders as contributors. Additionally, one or more extraneous alleles were detected in 10 of the 17 samples.

In conclusion, a comprehensive analysis on a large set of trace samples is currently being conducted to investigate the influence of contact time and recovery time on DNA recovered from doorknobs in burglary scenarios.

B144 Investigating the Dynamics of Trace DNA in a Burglary Scenario

Hailee Weiss, BS, Arcadia University, Norristown, PA; Edward Schikel, MBA, Montgomery County Detective Bureau, Norristown, PA; Megan M. Foley, PhD, Hamline University, St. Paul, MN; Fabio Oldoni, PhD, Arcadia University, Glenside, PA*

Learning Objectives: At the conclusion of this presentation, attendees will have a stronger understanding of how variables such as surface type, touch time, and recovery time affect the deposition of trace DNA.

Impact Statement: This presentation will impact the forensic science community by exploring the deposition and persistence of trace DNA deposits left via touch in a mock burglary scenario. The information collected and presented in this presentation will expand the knowledge of forensic scientists by aiding them in strategically choosing the most relevant surface types to effectively collect DNA samples following a break-in.

Abstract Text: With increasing advancements in DNA technology, investigators have begun to recognize the forensic relevance of trace DNA deposits left by offenders at the scene of a crime. More specifically, deposits of trace DNA left from an offender's touch have become a target for crime scene investigators.[1] Learning the proper means of collection and analysis of this type of DNA at a scene offers a unique motivation for further research. Researchers have identified several variables thought to affect deposits of trace DNA. Studies have been performed to better understand how surface type, touch time, and recovery time can affect the quantity of DNA yielded.[2,3] With a more complete understanding of how these variables may influence the deposition and persistence of trace DNA, investigators can utilize this information to effectively examine surfaces connected to burglary scenarios and collect pertinent trace DNA samples in the pursuit of justice.[4]

A mock burglary scenario was conducted using two surfaces: a plastic countertop (porous) and a metal drawer handle (non-porous). Each simulation consisted of one female as mock homeowner and one male as mock offender, with ten total pairs of participants. The female participant touched the surface for 20 minutes on two consecutive days to simulate consistent use by a homeowner. The male participant touched the surface for 30 seconds or 1 minute, in distinct simulations, after two days of contact by the female participant. Sample collection was done after one hour or six hours in distinct simulations. Cotton swabs (Puritan) were used to collect all samples via the double swab method. Extractions were done using the QIAamp DNA Investigator Kit and QIAshredder Kit. Quantification was performed using the Trio Quantification Kit on a QuantStudio Real-Time PCR system. Polymerase Chain Reaction (PCR) amplification of all samples was done using the GlobalFiler Amplification Kit and the Proflex 96-Well PCR System. Short Tandem Repeat (STR) fragments were separated with the SeqStudio Genetic Analyzer and profiles were analyzed with GeneMapper ID-X software v1.6. Reference buccal swabs were collected from all participants and DNA was extracted using Chelex resin. These samples were PCR amplified, separated, and analyzed using the same kits and instrumentation used for trace samples.

A series of 25 preliminary samples were collected showed that quantification values of samples collected from the plastic countertop ranged from 0.001 ng/ul to 0.676 ng/ul and quantification values of samples collected from the metal handle range from 0.002 ng/ul to 0.712 ng/ul. A mixed STR profile including both the mock homeowner and mock offender was obtained in 13 out of 25 (52%) of samples. Extraneous DNA was also detected in some of the trace samples. Further analysis of a larger dataset of trace DNA samples is currently in progress.

In conclusion, a more complete investigation into surface type, offender touch time, and recovery time and their effects on the deposition of trace DNA is being conducted to reveal how trace DNA evidence can be utilized by investigators in burglary scenarios.

B145 The Impact of Dissolvable Swab Technology for Single-Cell DNA Recovery From Forensic Evidence

Assa John, MS, Rutgers University, Camden, Camden, NJ*

Learning Objectives: After engaging with this presentation, participants will be able to: (1) describe the concept and potential benefits of dissolvable swab technology for forensic and clinical DNA sampling, (2) understand the role of calcium alginate as a biocompatible, dissolvable coating on conventional cotton swabs (3) evaluate the challenges and limitations encountered in developing dissolvable swabs for single-cell DNA recovery (4) recognize the importance of non-destructive sampling methods in forensic trace evidence collection, and (5) discuss the translational potential of laboratory-based innovations into field-ready forensic tools.

Impact Statement: This presentation introduces innovative dissolvable swab technology using calcium alginate coatings to enhance forensic DNA evidence collection. By reducing sample loss and enabling non-destructive single-cell DNA recovery, this approach addresses key limitations of traditional cotton swabs. Improving the integrity and yield of DNA samples can lead to more accurate forensic analyses, faster case resolutions, and stronger judicial outcomes, benefiting forensic practitioners and the broader criminal justice system.

Abstract Text: After attending this presentation, attendees will understand the limitations of conventional DNA evidence collection methods and how calcium-alginate-based dissolvable swabs can offer a non-destructive alternative for single-cell forensic analysis. This presentation will impact the forensic science community by introducing an innovative, dissolvable swab technology that enhances DNA recovery from individual cells, enabling more precise identification in complex forensic cases involving multiple contributors.

Though widely used, traditional cotton swabs often collect insufficient DNA and rely on destructive extraction methods that compromise single-cell integrity. This research proposes a novel swab fabricated from calcium alginate—a dissolvable biopolymer formed by combining sodium alginate and calcium chloride to coat cotton fibers. The swab design allows for efficient uptake and non-destructive release of cells.

The study is divided into two phases: (1) synthesis and fabrication of the dissolvable swab material, and (2) comparative analysis of the novel swab's performance against conventional swabs. The composite material was characterized using Fourier Transform Infrared (FTIR), Thermogravimetric Analysis (TGA), and Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS). Additionally, a Nepagene Video Microscope and hemocytometer were used to quantify the percentage cell capture and release, objectively measuring the swab's efficiency.

Results demonstrate that calcium-alginate dissolves cleanly, facilitating the release of cells by disrupting cell-to-matrix anchoring without compromising cellular structure. This research presents a transformative tool for forensic DNA collection and analysis, with potential to increase accuracy, minimize contamination, and improve crime scene investigation outcomes.[1-6]

B146 Time Since Deposition Signatures for Trace Biological Samples Using Cellular Autofluorescence

Gabrielle J. Wolfe, BS, Virginia Commonwealth University, Richmond, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: After this presentation, attendees will learn about a novel method for determining the Time Since Deposition (TSD) of touch epidermal cells that utilizes differences in their intrinsic autofluorescence. Attendees will also learn how these signatures can be incorporated into the operational workflow of forensic caseworking laboratories.

Impact Statement: This work can impact the forensic community by providing a new strategy for determining when biological material was deposited at a crime scene. This can not only increase the probative value of DNA profiles but also be used to screen evidentiary samples and identify those that are most likely to provide DNA profiles relevant to the investigation.

Abstract Text: Autofluorescence signatures are created from the excitation of endogenous fluorophores within cells. The wavelengths of fluorescence emissions and their relative intensity is primarily a function of each cell's biochemical composition. In epidermal cells derived from an individual's hands, autofluorescence profiles are driven by the relative abundance of various types of molecules such as keratins, flavins, and lipofuscins. After epidermal cells are deposited onto a substrate, their composition changes over time, which creates variations in the wavelengths and intensity of autofluorescence that can be used to reconstruct the time frame of deposition.

The goal of this study was to develop autofluorescence signatures for approximating TSD for "touch" or trace epidermal cell populations. To accomplish this, swabs of the palmar surface of 111 individuals were collected and allowed to age for anywhere between 0 days to approximately 3 years. Cell populations were then eluted from each swab into a phosphate buffer and analyzed immediately with flow cytometry without any other preparative treatments. Autofluorescence profiles were collected using five excitation lasers (355nm, 405nm, 488nm, 561nm, 640nm) and 64 fluorescent detection channels that recorded the intensity of the emission wavelengths (between 365nm and 829nm).

Results showed that increasing TSD of the sample did cause systematic changes in autofluorescence profiles within epidermal cell populations that were consistent across all contributor cell populations tested. TSD-driven variation was clearest when specific subpopulations were defined by morphological characteristics (e.g., forward scatter and side scatter values) as well as autofluorescence intensity within specific excitation channels, Ultraviolet (UV) and Violet (V). Within this subpopulation, samples with TSD greater than 1 year could be easily differentiated from younger TSD samples based on the high proportion of cells (≥ 70%) fluorescing over a threshold intensity of 400,000 RFU in the V-4 detection channel. Conversely, epidermal samples with TSD less than a week could be differentiated from all other TSD samples based on the median percentage of cells over threshold, which increased from approximately 50% for samples less than one week old to 81% for those with TSDs greater than 1 year. Additionally, cell populations with a TSD above 1 year had increased intensity of autofluorescence in the UV channel compared to those with a TSD less than a year as well as a ratio of Yellow-Green (YG-2) to Ultraviolet (UV-3) autofluorescence intensity that could easily be distinguished for samples with a TSD less than one week compared to those between 1.5 and 3 years.

Overall, these results suggest that autofluorescence profiles can be used to provide probative context for biological samples. Additionally, this information may be used to quickly identify whether trace biological material was deposited recently (i.e., < 1 week) or more than a year prior to collection which may be relevant to the investigation. Moreover, spectral profiles can indicate whether samples represent mixtures of multiple biological deposits based on the presence of more than one autofluorescence peak indicating two different TSDs in the same sample.

B147 An Investigation of DNA Contribution From Trace Samples Recovered From a Screwdriver Used as a Murder Weapon

Lauren Kennedy, BS, Arcadia University, West Deptford, NJ; Mechthild Prinz, PhD, John Jay College of Criminal Justice, New York, NY; Tacha Hicks, PhD, UNIL, Lausanne, Vaud, Switzerland; Fabio Oldoni, PhD, Arcadia University, Glenside, PA;*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how surface type and recovery time affects the amount of DNA obtained from a mock murder weapon.

Impact Statement: This presentation will impact the forensic science community by exploring the persistence of DNA on a screwdriver used as a weapon as well as how recovery time affects the amount of recoverable DNA.

Abstract Text: Trace DNA can be left behind on the murder weapon during a homicide. Anytime someone comes in contact with another person or an object, there is a possibility that they will leave DNA behind. There is no fixed quantity of DNA as different people will deposit differing amounts of DNA upon contact.[1] A person's "shedder status" refers to how much of their own DNA is left behind after touching an object.[2] While a person's shedder status is innate, there are certain factors that affect how much DNA can be recovered from a sample such as manner of contact, surface type, and recovery time. This study is designed to explore how surface type of a screwdriver and the recovery time affects the persistence of DNA as well as the quantity and quality of Short Tandem Repeat (STR) profiles obtained.

A simulation was set up where a participant was asked to aggressively swing a screwdriver ten times at a target. Fourteen volunteers (8 females and 6 males) were recruited with all 14 volunteers performing the simulation with both a screwdriver with a rubber handle and a plastic handle. In total, there will be 84 samples collected from the simulations. Each participant performed the simulation three times using both their dominant and non-dominant hand in order to observe recovery times of 6 hours, 24 hours, and 48 hours post simulation. Each participant will have their own screwdrivers, but they will not be cleaned in between simulations.[3] Reference samples from all volunteers were collected from buccal swabs and extracted using Chelex resin. Trace samples were collected by Puritan double cotton swabs, extracted using the QIAamp DNA investigator kit and QIAshredder columns, quantified using the Trio Quantification kit on a QuantStudio Real-Time PCR system. Trace and reference samples were Polymerase Chain Reaction (PCR) amplified using the GlobalFiler Amplification kit on the Proflex thermocycler. The STR fragments were then separated using the SeqStudio Genetic Analyzer and STR profiles were analyzed with the GeneMapper ID-X software v1.6.

Preliminary results on 16 samples out of the 84 showed that the quantification values obtained were within the 0.055 ng/µl - 0.161 ng/µl range. The samples collected from the screwdriver with a plastic handle and handled using dominant hands generated the largest quantification values (0.151 ng/µl – 0.161 ng/µl) regardless of recovery time. The samples obtained using the more porous rubber handle yielded lower quantification values (0.066 ng/µl – 0.123 ng/µl)4. Mixed STR profiles were observed. In all samples, the mock offender was found to be the major contributor along with few additional extra alleles detected.

In conclusion, an investigation of trace samples obtained from a screwdriver used as a murder weapon is in progress to reveal the effect that surface type and recovery time has on the persistence of DNA obtained from mock-murder weapons.

B148 Indirect DNA Transfer to Duct Tape Rolls and Fidget Blasters Stored in Cars

Rachel Chan, MS, John Jay College of Criminal Justice, New York, NY; Yuching Chung, MS, John Jay College of Criminal Justice, New York, NY; Mechthild Prinz, PhD, John Jay College of Criminal Justice, New York, NY*

Learning Objectives: Attendees will learn that items stored in cars can have detectable levels of human DNA without direct contact. They will be informed that larger and rougher duct tape roll surfaces accumulate more DNA than the smoother plastic fidget blasters.

Impact Statement: Data on the transfer, prevalence, and persistence of trace DNA are important for the assessment of the probative value of DNA evidence. Indirect DNA transfer to stored items is sometimes used as an explanation for the presence of a defendant's DNA. Forensic scientists and legal professionals can refer to our dataset to evaluate a claim like this.

Abstract Text: This study evaluated the amount of detectable background DNA on fidget blasters (toy guns) and duct tape rolls stored inside a vehicle for seven days. Two clean fidget blasters and unused duct tape rolls were given to 12 volunteers. Using gloves, the volunteers placed the fidget blasters and duct tape in two different locations (under the driver's seat for both items, the glove box for the fidget blaster, and the trunk for the duct tape) in their car. After the items were returned, they were swabbed and subjected to DNA extraction, human DNA quantitation, and Short Tandem Repeat (STR) genotyping. For the fidget blasters, we swabbed the trigger, the slide, and the grip. For the tape roll, we swabbed the cardboard inside, the outside, and both flat sides.

In general, the DNA concentrations for the duct tape samples were higher than for the fidget blaster samples, which is likely due to the difference in size and surface texture. For the smooth plastic fidget blasters, only 19% of the samples had a DNA concentration of greater than or equal to 0.002 ng/µL and were eligible for Polymerase Chain Reaction (PCR). The rougher and relatively larger grip area had the most DNA, whereas 89% of duct tape samples were eligible for PCR. Results on the duct tape reflect the larger and rougher surface area.

STR profiles ranged from "not suitable for comparison," to partial to full genotypes. STR success correlated to DNA available for amplification. Only 7% of the fidget blaster samples, but 71% of the duct tape samples, were suitable for comparison to the vehicle owner. Most samples on both items were DNA mixtures. The vehicle owner was the source of all but one single source profile on the duct tape, and the major component for all but one deducible mixture. The owner was excluded in 15% of the samples. With only five results on the fidget blasters, the owner was present in four and excluded from one.

The study demonstrates that the indirect deposition of DNA in a vehicle is possible, and the amount transferred is dependent on the surface texture of the stored item. Metal surfaces have different properties, and our results cannot be applied to metal firearms. The most likely source for the DNA on the duct tape is the accumulation of dust and skin flakes in the car's carpet. Variables that should be controlled in future studies include the number of occupants, the size of the car, and the frequency of use and cleaning.

B149 Evaluating the Impact of Surface Type and Swab Moistening Conditions on Trace Collection Efficiency

Anna Franzoni, MSc, Copan Italia Spa, Brescia, Lombardia, Italy; Michele Rosso, PhD, Copan Italia SpA, Brescia, Lombardia, Italy*

Learning Objectives: This presentation will explore how different surface types and swab moistening volumes affect the efficiency of forensic trace collection. Attendees will gain insights into how to optimize DNA recovery from porous and non-porous surfaces.

Impact Statement: This study offers practical guidance for improving trace collection in forensic caseworks. By highlighting conditions that enhance yield across common substrates where traces can be deposited, the findings support evidence-based sampling protocols that can increase the success rate of forensic analyses.

Introduction: Efficient recovery of biological traces is crucial in forensic investigations, especially when dealing with low DNA quantities. Swabbing is the most used collection method, but gaps remain on how to optimize sampling to maximize DNA yield.[1] Key factors influencing trace recovery include the type of surface where the trace is deposited and the moistening condition of the swab.[2] This study evaluated the performance of dry and pre-moistened 4N6FLOQSwabs in collecting semen traces from different porous and non-porous surfaces.

Materials and Methods: Semen traces (15 µl of neat semen diluted 1:3 and 1:300) were deposited on metal, wood, and cotton fabric and left to dry overnight. For each surface, 30 traces per dilution were collected using two Copan 4N6FLOQSwabs: the regular swab and the smaller, triangular subungual swab. In particular, for each surface and semen dilution, 3 traces were collected dry and 12 with 4N6FLOQSwabs pre-moistened at increasing volumes (15µl, 30µl, 100µl and full saturation for regular; 5µl, 15µl, 30µl and full saturation for subungual), using three swabs per volume conditions. Samples were air-dried for 30 minutes, extracted with PrepFiler Express, and quantified using Quantifiler Trio. Controls, all processed using the same extraction and quantification methods, included clean swabs, surface swabs before trace deposition, swabs directly spotted with semen dilutions and neat semen dilutions. Statistical analysis was performed with Minitab v22.

Results: DNA recovery varied depending on the surface type, with metal yielding the highest quantities, followed by wood and cotton fabric. For both semen dilutions and 4N6FLOQSwabs types, pre-moistened swabs yielded significantly more DNA than dry ones across all surfaces ($p < 0.05$). The only exception was the 1:3 semen dilution collected with subungual 4N6FLOQSwabs, where no significant differences were observed between dry versus wet swabbing or among the various pre-moistening volumes.

On metal, excluding dry swabbing values from the analysis, pre-moistening volume did not significantly impact DNA recovery, except for the 1:300 semen dilution. In this case, significantly higher yields were obtained with fully saturated regular 4N6FLOQSwabs compared to 15µl ($p < 0.05$), and with 15µl and 30µl pre-moistened subungual 4N6FLOQSwabs outperformed those fully saturated ($p < 0.05$).

On wood, for both semen dilutions and with both 4N6FLOQSwabs, DNA recovery generally increased with higher pre-moistening volumes, with several statistically significant differences. Excluding dry swabbing values from the analysis, fully saturated subungual 4N6FLOQSwabs outperformed all other volumes for the 1:3 semen dilution recovery ($p < 0.05$). For the 1:300 semen dilution, full saturation of subungual 4N6FLOQSwabs yielded more DNA than 5µl and 15µl ($p < 0.05$), with no significant difference versus 30µl.

On cotton fabric, fully saturated 4N6FLOQSwabs consistently gave the highest yields across the two semen dilutions and swab types ($p < 0.05$), except for the 1:3 dilution with subungual 4N6FLOQSwabs, as noted above.

Conclusion: Pre-moistened 4N6FLOQSwabs generally outperformed dry swabbing in DNA recovery across all tested surfaces. While varying pre-moistening volumes had minimal impact on the collection efficiency from metal, higher volumes tended to enhance yields on wood and cotton fabric. A more structured evaluation is needed to refine wetting protocols.

B150 The Evaluation of a Mini-Vacuum Device for the Collection for Low-Level Samples

Kayli N. Carrillo, BS, Sam Houston State University, El Paso, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will learn about the Squeegee-Aspirator for Large Sampling Area (SALSA) device as an alternative collection method, its potential integration into forensic workflows, and its applicability across various forensic casework sample types.

Impact Statement: This presentation will impact the forensic science community by introducing a hand-held mini-vacuum device as a novel DNA collection method for forensic sample types and demonstrating its effectiveness compared to traditional cotton swabbing.

Abstract Text: DNA collection from probative samples is critical to the successful generation of Short Tandem Repeat (STR) profiles. Cotton swabs are the most common method for collection, due to their ease of use and cost-effectiveness. However, DNA is known to remain trapped within the cotton fibers, limiting recovery efficiency.[1]

Alternative collection techniques have been explored, including vacuum-based systems. For example, the microbial wet-vacuum (M-Vac) has demonstrated effective DNA recovery from a variety of substrates.[2] A novel device, the SALSA, originally used for sampling low-level microbiomes from spacecraft manufactures, shows potential for forensic use. This SALSA device consists of a 3D-printed, patent-pending manifold that is used in conjunction with a battery-operated aspirator for vacuuming. A wetting agent, such as sterile water, is sprayed onto the sampling surface, and the liquid is vacuumed into a 2ml collection tube, which can be easily integrated into existing manual or automated forensic DNA extraction workflows.

The first goal of this study was to develop a workflow compatible with forensic laboratories. Two approaches were evaluated: direct amplification of the vacuumed solution without purification and extraction and purification of the solution using the EZ2 Connect Fx automated platform. Glass slides (n = 10) and fabric swatches (n =10) were spiked with 10ng and 1ng buccal suspension to compare the two workflows with the traditional cotton swab method. DNA quantification and STR analysis results showed that purification of the vacuumed liquid yielded DNA quantities and profile completeness comparable to those obtained with cotton swabs across both surface types.

After establishing the EZ2 Connect compatible workflow, the second objective was to evaluate the SASS device in comparison to cotton swab for mock casework samples, including: water bottles, clothing collars, steering wheels, held knife handles, saliva-spiked bottles, semen dilutions on fabrics, and blood dilutions on glass slides. All samples were extracted and purified using the Investigator Large-Volume RT Protocol on the EZ2 instrument, quantified using Quantiplex Pro, and amplified using the Investigator 24plex kit. The SALSA device and cotton swabs yielded comparable quantification and STR profiles across most sample types. Notably, in semen dilution samples, the SALSA device produced higher STR profile recovery from a 1:1000 dilution compared to cotton swabs. Overall, this study demonstrated the potential of the SALSA device as an alternative DNA collection method that can be seamlessly integrated into forensic laboratory workflows.

B151 The Influence of Primary Contact Deoxyrinonuleacic Acid (DNA) on the Detection of Passively Transferred DNA in Forensic Casework Environments

Lauren T. Watts, BS, Virgina Commonwealth University, Richmond, VA; Kimberly Freeman, MFS, Virginia Department of Forensic Science, Norfolk, VA; Susan A. Greenspoon, PhD, Virginia Department of Forensic Science, Richmond, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: After attending this presentation, attendees will gain a clearer understanding of the mechanisms and conditions by which passive DNA transfer occurs and its influence in forensic DNA interpretation. Attendees will also understand the influence primary transfer has on the detection of passive DNA and its suitability for interpretation in casework samples.

Impact Statement: This presentation will increase the community's understanding of passive DNA transfer and how readily detectable it can be. These findings will improve the accuracy and transparency of conclusions made by DNA analysts in casework for trace DNA samples. Additionally, this research will also support legal professionals and jurors in understanding that the presence of DNA alone does not inherently indicate direct involvement in a crime, thereby promoting more scientifically informed arguments.

Abstract Text: DNA transfer is generally classified into two overarching categories based on the mechanism of deposition: direct and indirect transfer. Direct transfer occurs when DNA is deposited through immediate physical contact between an individual and an object.[1] In contrast, indirect DNA transfer refers to the unintentional deposition of DNA without deliberate involvement from the donor, typically through the shedding of epithelial cells, hair, and body fluids during routine daily activities.[2-5] As the interpretation of trace DNA becomes increasingly complex, and amid existing gaps in empirical data, legal systems are placing greater scrutiny on how DNA is deposited and what its presence on evidence implies.[5] While the forensic community has established that direct and indirect DNA transfer can occur under everyday circumstances, the extent to which passively transferred DNA can be detected and interpreted in the presence of primary DNA remains poorly understood, especially when evaluated under casework standards. This study aims to investigate whether DNA deposited through primary means can suppress, enhance, or otherwise influence the detection of passively transferred DNA in ways that could impact forensic interpretation. To explore this, a series of test items were placed in both open office environments and enclosed vehicle settings and left undisturbed for seven days while participants continued with normal daily activities. DNA profiling was then conducted following validated protocols set forth by the Virginia Department of Forensic Science (VA DFS).

Preliminary results suggest that passively transferred DNA can be consistently detected, though the quantity and quality of profiles vary greatly based on environmental conditions and the presence of active transfer DNA. While passive transfer alone produces DNA levels well below the threshold for probative comparison at less than 0.025ng, primary handling creates a biological matrix that captures passive DNA, thus elevating the amount of DNA present for comparison. Passive DNA profiles alone appear at first glance to be single-sourced, created through a complex mixture of drop-out, drop-in, and stochastic effects. In comparison, profiles gathered in the presence of actively transferred DNA, particularly in closed environments, show consistent mixtures that are able to be deconvoluted into a major and minor profile that meet criteria for the Combined DNA Index System (CODIS) uploading. These findings suggest that under certain conditions, passive DNA may not only persist, but may also be amplified by the presence of primarily transferred DNA to the extent that it results in a complex mixture that requires further resolution. This demonstrates the critical importance of understanding low-level DNA transfer mechanisms to impart accurate forensic interpretation.

B152 Exploring the Persistence and Transfer of DNA Under Fingernails in Mock Physical Assaults

Jean P. Poulson, BS, Arcadia University, Doylestown, PA; Sarah Gino, MD, Department of Health Sciences, University of Eastern Piedmont, Novara, Piemonte, Italy; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Anna Franzoni, MSc, Copan Italia Spa, Brescia, Lombardia, Italy; Fabio Oldoni, PhD, Arcadia University, Glenside, PA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the persistence and two-way transfer of trace DNA following a mock physical assault scenario.

Impact Statement: This presentation will impact the forensic science community by exploring the persistence and transfer of DNA under the fingernails of a victim following mock physical assault scenarios. This presentation will expand our current knowledge on the detection of an offender's DNA under a victim's fingernails and the detection of a victim's DNA on an offender's forearm.

Abstract Text: Trace DNA analysis has been an important forensic method for investigating DNA left at the scene of a crime, but few studies have explored the mechanisms of two-way transfer and the persistence of trace DNA.[1,2] The persistence and transfer of trace DNA is difficult to quantitatively measure particularly when there is a mixed profile.[3] Analyzing trace DNA is pertinent in cases of physical assaults where DNA is often deposited on the body of the victim.[4] The touch DNA recovered from a victim's body preceeding an assault may aide in the identification of the offender.[5] This study is designed to investigate the persistence and two-way transfer of trace DNA under the fingernails and on the forearms in a physical assault scenario.

Simulations of physical assaults were conducted with a female mock victim lightly scratching the forearm of a male mock offender. Twelve pairings of volunteers (6 females and 6 males) were recruited for either 5 scratches or 10 scratches. The "victim's" dominant hand and the forearm of the "offender" were sampled at 0 and 3 hours in distinct simulations. Each pair of volunteers were involved in each simulation combination for a total of 16 samples/ pair. Reference samples were collected from buccal swabs and extracted utilizing Chelex resin. Trace samples from the fingernails were collected with Copan subungual dry swabs, and samples from forearms were collected by Puritan cotton swabs. The samples were extracted using the QIAmp DNA Investigator Kit and QIAshredder Kit and quantified using the Trio Quantification kit on a QuantStudio ProFlex 96-well Reverse Transcription Polymerase Chain Reaction (RT-PCR) system. Samples were amplified using the GlobalFiler Amplification kit. The Short Tandem Repeat (STR) fragments were separated using the SeqStudio Genetic Analyzer. The Yfiler Plus Kit will be utilized after the initial fragmentation analysis to amplify the Y-STR markers of the male profile, if necessary, to improve resolution of DNA mixtures that include small quantities of male DNA. The STR profiles will be analyzed with the GeneMapper ID-X software.

Overall, the preliminary results on an initial set of 32 trace samples showed that the quantification values of samples collected from the victim's fingernails ranged between 0.007 ng/ µl and 0.486 ng/ µl. The trace samples collected from the offender's forearms ranged between 0.003 ng/ µl and 0.351 ng/ µl. A mixed STR profile was observed in 62.5% (15/24) fingernail samples and 75% (6/8) forearm samples. A general decrease in the proportion of the offender's DNA in relation to the victim's DNA was observed over time from trace samples collected from the victim's fingernails, which is in line with the previous study conducted by Damour et. al.[2] It was also noted that there was a general decrease in the proportion of the victim's DNA in relation to the offender's DNA over time from two-way trace samples collected from the offender's forearms.

In conclusion, a comprehensive investigation of 140 trace samples is in progress to reveal persistence and the two-way transfer of DNA from the mock offender to mock victim's fingernails and vice versa.

B153 ChronoGenetics: Beyond Identity—Reconstructing the When, Where, and Why of DNA Evidence

Tasneem Saeed Abdelaziz, Faculty of Science Banha University, Shebin Elkom, Al Minufiyah, Egypt*

Learning Objectives: Attendees will learn how to estimate the age of a DNA sample and assess its relevance to a crime scene using degradation patterns and environmental sensor data.

Impact Statement: ChronoGenetics challenges the limits of DNA evidence by revealing not just who, but when and how. It invites forensic science to listen deeper, not match.

Abstract Text: DNA analysis has transformed forensic science, offering investigators the ability to identify individuals with high accuracy. Yet, despite its power, DNA evidence is limited when interpreted without context. While it can determine *who* contributed a biological trace, it cannot independently reveal *when* it was deposited, the conditions it endured, or whether it is probative to a specific event.[1]. In environments where DNA can persist or transfer, these gaps may mislead investigations and even judicial outcomes.[2]

This study introduces a prototype portable system that integrates DNA profiling with contextual metadata, including time, location, and environmental exposure. Molecular analysis focuses on DNA degradation patterns—such as fragment length reduction and allelic signal loss—compared against reference degradation profiles derived from both experimental work and published studies.[3,4] These comparisons enable estimation of deposition intervals and assessment of environmental influences on DNA traces. The system also records contextual data automatically. Collection time and geographic location are digitally logged to reduce reliance on manual records, minimizing transcription errors. Environmental parameters such as temperature and humidity, which are known to affect DNA persistence, are simultaneously monitored.[5] This integration provides an objective framework that extends molecular analysis with reproducible contextual information.

Field simulations were used to test the approach. DNA samples were placed under shaded and sun-exposed outdoor conditions, then analyzed after several hours in elevated temperatures. Exposed samples exhibited accelerated degradation, including fragment loss and allelic drop-out, in contrast to shaded controls. These results aligned with published findings on environmental DNA damage and validated the system's ability to capture meaningful contextual variation.[5]

The value of this work lies in establishing a methodological framework, not in promoting a commercial product. By integrating genetic and contextual data, the approach advances forensic interpretation beyond simple identification. It enables investigators to better evaluate whether a DNA trace is relevant evidence or background noise, thereby reducing risks of misinterpretation. In conclusion, coupling DNA profiling with temporal, spatial, and environmental metadata strengthens the reliability of forensic reconstruction. This framework has the potential to safeguard accuracy and fairness in casework, particularly in complex scenarios where the relevance of DNA evidence is contested.

B154 Method Development for Interpreting DNA Mixtures From SNP Sequencing Data

Betzaida L. Maldonado, MSFS, University of Colorado Anschutz Medical Campus, Aurora, CO; Christopher R. Gignoux, PhD, University of Colorado Anschutz Medical Campus, Aurora, CO*

Learning Objectives: The goals of this presentation are to: (1) describe the key challenges of interpreting Single Nucleotide Polymorphism (SNP) data and explain how these differ from traditional Short Tandem Repeat (STR) analysis; (2) identify critical variables that influence the interpretation of SNP DNA mixtures; (3) gain an introductory understanding of how joint likelihood models can be applied to SNP mixture data; (4) evaluate the impact of developing mixture interpretation methods for sequencing-based forensic data; and (5) explore how SNP mixture interpretation supports applications in investigative genetic genealogy.

Impact Statement: Currently, no established or widely accepted guidelines exist for interpreting SNP mixture data. Our research evaluates the characteristics and patterns of SNP mixture data and introduces a likelihood model that deconvolutes two-person mixtures, especially when a known reference sample is available. By advancing the forensic science community's understanding of SNP mixture data, we aim to empower crime labs to implement SNP technology and pave the way for the interpretation of SNP mixtures in genetic genealogy searches.

Abstract Text: The increased sensitivity of genetic technologies to detect microscopic quantities of DNA has allowed forensic scientists to generate DNA profiles from previously untested evidence items. This same sensitivity has led to a growing number of samples containing DNA from multiple individuals, making mixture interpretation one of the most significant challenges in forensic DNA analysis. In the last decade, these challenges have been addressed using probabilistic genotyping software that can aid in mixture interpretation for Short Tandem Repeats (STRs) - which are the variable DNA regions traditionally tested in crime labs. However, there is no current or established methods for the interpretation of Single Nucleotide Polymorphisms (SNPs). This limitation hinders scientists from making conclusions in cases where SNP data is used, including cases involving unidentified remains and investigative genetic genealogy (IGG). Here, we evaluate the extent to which mixture proportions affect our ability to detect two- and three-person mixtures and propose a method that can be used to separate two-person mixtures, particularly when a known reference sample is available. Using simulation studies, we develop a joint likelihood model that, when maximized, can infer the alleles of an unknown contributor in two-person mixtures of SNP data, as well as the relative contribution to the overall SNP pool. Extending mixture interpretation methods to whole-genome sequencing enables a broader application of SNP data in forensic investigations, both by expanding the pool of samples eligible for genetic genealogy and by supporting crime labs as they adopt SNP technology in routine casework.

B155 Enhancing Forensic DNA Interpretation: A Combined STR-Microhaplotype Framework for EuroForMix

Natalie N. Holder, BS, George Washington University, Alexandria, VA; Abigail K. McDougall, BS*, George Washington University, Washington, DC; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Zack Beyerl, MFS, Bode Technology, Washington, DC*

Learning Objectives: Attendees will learn a proof-of-concept method for combining and analyzing Short Tandem Repeat (STR) and Microhaplotype (MH) data within the probabilistic genotyping software EuroForMix. They will gain an understanding of how this integrated marker approach enhances mixture deconvolution and consistently produces higher likelihood ratios than STRs or MHs alone, ultimately enabling more accurate and robust interpretation of complex DNA mixtures.

Impact Statement: This presentation advances forensic DNA analysis by demonstrating that probabilistic genotyping software can be adapted to jointly process MH and STR data. This capability will be particularly valuable as new Next Generation Sequencing (NGS) assays incorporating both marker types are developed. Such combined assays will improve mixture deconvolution through the sensitivity of MHs while preserving compatibility with legacy STR profiles generated by capillary electrophoresis, enabling backward compatibility and broader casework utility.

Abstract Text: STR polymorphisms are the standard markers for forensic DNA analysis due to their high discriminatory power.[1] However, they have limitations in resolving complex, imbalanced mixtures, where stutter artifacts can mimic minor contributors, and shorter alleles may be preferentially amplified.[2,3] In contrast, MHs are emerging sequence-based markers that do not produce stutter and are not subject to preferential amplification.[4] MHs offer greater sensitivity for detecting minor contributors and have been shown to yield more alleles in such mixtures compared to STRs. Several studies report that MHs can produce equal or higher likelihood ratios in mixture deconvolution.[3]

Probabilistic genotyping (PG) software like EuroForMix uses statistical modeling to interpret complex DNA mixtures.[5] While EuroForMix has been used with both STRs and MHs individually, the integration of both marker types has not been explored. This study investigates whether STR and microhaplotype data can be combined and analyzed in EuroForMix for mixture deconvolution and Likelihood Ratio (LR) generation.

A 43-plex assay developed as part of a separate effort was selected for this experiment. The 43 loci were purposely selected for absence of linkage disequilibrium with CODIS STRs. Microhaplotypes sequence variants were converted into numerical values, to align with STR data formatting for allele frequency tables, reference genotypes, and evidence files equating RFU values to sequence coverage. With EuroForMix we generated simulated two- and three-person DNA mixtures with the Combined DNA Index System (CODIS) STRs and the MH 43-plex individually. For two-person mixtures, we simulated contributor ratios of 1:1, 1:2, and 1:4. For three-person mixtures, we simulated ratios of 1:1:1, 10:5:1, and 10:5:5. After generating the simulated data, we created a combined mixture file, integrating both STR and MH data to simulate a single, unified assay. EuroForMix was then used to calculate LRs for across all mixture scenarios with STRs and MHs only and with the combined loci.

Preliminary data indicates that EuroForMix is compatible with combined STR and microhaplotype assays. Across ten simulated mixtures, as expected the combined dataset consistently produced higher LRs than either STR or MH data alone. For example, for the 1:1:1 mixture, the combined assay produced a LR of 3.69E238 compared to a LR of 6.11E33 using STRs and a LR of 5.55E54 using MHs alone. On average, testing for the ground truth, the combined assay's LRs were 87 orders of magnitude greater than those with STRs, and approximately 48 orders of magnitude greater than with microhaplotype. These preliminary results suggest that a combined STR and MH assay, currently under development in our lab, could be effectively analyzed using EuroForMix. While further optimization is needed for casework implementation, including refinement of stutter modeling, inter-locus balance, and degradation effects, the demonstrated compatibility of EuroForMix with this integrated approach provides strong evidence that combining STRs and MHs yields more informative likelihood ratios and enhances the accuracy of mixture interpretation.

B156 Optimized Silica Column-Based Extraction for the Capture of Highly Degraded Nuclear DNA From Rootless Hairs

Mia Gale, BS, The George Washington University, Washington, DC; Vinalon Mones, MFS, The George Washington University, Washington, DC; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Helene D. Douglas, BSc, The George Washington University, Washington, DC; Elaine Lewis, PhD, The George Washington University, Washington, DC*

Learning Objectives: Attendees of this presentation will learn about an optimized extraction method designed to recover highly degraded nuclear DNA from rootless hairs. This enables Short Tandem Repeat (STR) analysis of a sample type that is typically challenging for nuclear DNA profiling.

Impact Statement: Rootless hairs pose a significant challenge in forensic DNA analysis due to the limited quantity and highly degraded state of the nuclear DNA. As a result, mitochondrial DNA (mtDNA) is at times used despite its lower discriminatory power compared to STRs. This study presents an optimized method that improves the binding efficiency of degraded DNA fragments to silica membranes, resulting in greater allele recovery from STR loci with small amplicons.

Abstract Text: Rootless hairs are commonly found at crime scenes and are a challenging sample type for forensic analysis.[1] Without the root, nuclear DNA must be extracted from the hair shaft, where it is typically low in quantity and degraded. Consequentially, mtDNA is often targeted for its higher copy number despite STRs remaining better for individualization.[1,2] Commercial forensic DNA extraction kits are not optimized for highly degraded DNA, as STR analysis typically requires fragments over 100 base pairs. The goal of this project is to optimize the QIAamp DNA Investigator Kit for the capture of highly degraded DNA from hair shafts. The small fragments captured can be amplified with reduced-size STR kits, such as the AmpFLSTR MiniFiler kit, which are designed for low-quality DNA.

Hair shafts were collected from 90 donors (The George Washington University Institutional Review Board [GWU IRB]: NCR245802) and processed with the optimized extraction method, designated the "PB method," which uses Buffer PB instead of Buffer AL and EtOH for the binding of DNA to the silica column. The ratio between lysate and binding buffer was also increased, therefore enhancing binding of smaller DNA fragments. Additionally, samples were centrifuged at a lower speed, compared to the manufacturer's protocol, with the lowest acceleration ramp possible to increase the exposure of the lysate to the membrane and enhance DNA binding. Using the PB method, DNA fragments in the range of 50–150 base pairs were captured at an increased rate. However, this approach also increased the co-elution of inhibitors, requiring an additional purification step using the Monarch Spin PCR & DNA Cleanup Kit.

Results show that DNA quantity and degradation levels from the hair shafts varied among individuals. The average total DNA yield was 100 pg, with 39% of the 90 donors yielding more than 50 pg of DNA from a 5 cm segment of hair. Fifty picograms served as the threshold to determine whether a sample would proceed to amplification. Degradation was observed in 83% of the samples, indicated by a Degradation Index (DI) greater than 3. Notably, 33% of donors had drop out of the large autosomal, indicating extreme degradation. There was no clear correlation between DI and total DNA quantity. However, at very low DNA levels, stochastic variation in the Polymerase Chain Reaction (PCR) process can obscure trends, and multiple replicates are recommended for reliable interpretation.

A subset of 26 donors with total DNA quantities above 50 pg underwent STR amplification using the AmpFLSTR MiniFiler kit. Of these, 46% produced nine or more alleles, 23% produced from eight to five alleles, and 31% produced four alleles or less. Importantly, all 26 samples resulted in the recovery of at least two alleles. As expected, higher DNA quantities were generally associated with a greater number of recovered alleles, supporting a positive correlation between DNA input and STR allele yield. This optimized method significantly improves DNA recovery from rootless hairs, supporting their expanded use as a viable and previously underutilized source of nuclear DNA in forensic casework.

B157 The Extraction and Genotyping of Nuclear DNA From Rootless Hair Shafts Using Capture Hybridization

Daniele S. Podini, PhD, The George Washington University, Washington, DC; Elaine Lewis, PhD, The George Washington University, Washington, DC; Helene D. Douglas, BSc, The George Washington University, Washington, DC; Vinalon Mones, MFS, The George Washington University, Washington, DC; Mia Gale, BS, The George Washington University, Washington, DC*

Learning Objectives: Attendees will learn about a method to extract and genotype nuclear DNA from rootless hair shafts using an optimized Next-Generation Sequencing (NGS) workflow incorporating hybridization-based target enrichment. They will understand how to evaluate extraction efficiency, assess Single Nucleotide Polymorphisms (SNP) recovery, and interpret fragment degradation patterns to support human identification from rootless hair samples.

Impact Statement: This presentation will update forensic practitioners on methods to extract and genotype nuclear DNA from rootless hair shafts using low-input, high-degradation-tolerant methods. Attendees will learn how this workflow may be applicable to casework scenarios involving hair samples, expanding the types of evidence that can yield individualizing DNA profiles. This advancement has the potential to enhance investigative outcomes and support the identification of individuals from shed hair where traditional Short Tandem Repeat (STR) profiling is not feasible.

Introduction: Hair is a common form of biological evidence at crime scenes, but its forensic utility is limited using conventional DNA analysis methods. Hair contains both mitochondrial and nuclear DNA; however, mitochondrial DNA lacks the discriminatory power needed for individualization. Nuclear DNA, which enables individual identification, is typically present in very low quantity and is highly degraded in shed (rootless) hairs.[1-3] As a result, traditional STR-based profiling—which relies on intact DNA fragments—is often unsuccessful.[4] In contrast, SNP and small microhaplotype genotyping, which require shorter DNA fragments, offers a promising alternative but has not been implemented due to challenges in recovering sufficient nuclear DNA from hair shafts. This study aimed to develop and optimize a robust workflow for the recovery of nuclear DNA from rootless hair shafts and to enable SNP genotyping through NGS and hybridization-based target enrichment.

Methods: Several extraction protocols were evaluated, with a modified BioChain cell-free DNA (cfDNA) method selected for its ability to recover DNA without requiring carrier RNA. Library preparation was conducted using the Takara ThruPLEX DNA-Seq Kit, suitable for low-input, degraded DNA. A custom probe panel targeting 818 SNPs, including 73 small microhaplotype pairs, was developed using Daicel Arbor Biosciences technology. Libraries underwent two rounds of hybridization-based target capture and were sequenced on an Illumina MiSeq platform. Data analysis included fragment size profiling, read alignment, and SNP coverage assessment.

Results: Nuclear DNA was successfully extracted from 75 donor samples, with ~37% of 5 cm hair segments yielding ≥50 pg of DNA. Five samples were fully processed through the optimized workflow. SNP recovery ranged from 7% to 42% of targets (≥10× coverage), with no clear correlation between input quantity and locus recovery. Fragment length distributions , from 30-400 bp, confirmed severe degradation, and a ~10.4 bp periodicity in read lengths was observed, suggestive of nucleosome-related degradation patterns. While coverage was variable, even samples with the lowest SNP recovery may still yield informative genotype data for identification purposes assuming a reference sample is available.

Conclusion: This study demonstrates that informative SNP genotyping is achievable from rootless hair using a carefully optimized extraction and target capture workflow. The approach offers new possibilities for forensic identification from previously intractable evidence types and supports broader application of NGS-based methods in forensic casework.

B158 The Impact of Maggot Feeding on Tissue Time Point Collection and DNA Recovery Success From Decomposing Rat (*Rattus Norvegicus*) Tissues

Ashley G. Morgan, PhD, University of New Haven, West Haven, CT; Samantha J. Sawyer, PhD, Henry C. Lee College of Criminal Justice and Forensic Sciences, University of New Haven, West Haven, CT*

Learning Objectives: Attendees will learn how maggot activity impacts DNA recovery from decomposing rat (*Rattus norvegicus*) tissues over time. Additionally, attendees will better understand the effect of time point of tissue collection and its impacts on DNA recovery.

Impact Statement: This presentation will impact the community by providing additional evidence for timely collection of soft tissue samples. Furthermore, the community will understand the impact of maggot activity on DNA recovery from decomposing rat tissue (*Rattus norvegicus*).

Abstract Text: Whether due to mass disaster or questionable circumstances, recovery and identification of decomposing remains is challenging. Initial recovery of human remains requires responding personnel to preserve possible evidence and maintain the integrity of the individual to improve likelihood of identification. Traditional methods of identification of recently deceased remains include visual identification, fingerprints, or dental records. In situations when traditional methods do not yield an identification, DNA testing may be performed. Ideal samples for DNA identification include soft tissue and blood; however, in more advanced decomposing remains, soft tissue and blood may be impacted by larval and insect activity. Such insect activity may degrade DNA within soft tissues due to enzymatic secretions from the maggot mass. Additionally, high insect activity may lead to complete soft tissue consumption, leaving only bony tissues.

This study investigated the impacts of maggot activity on freshly decomposing rat (*Rattus norvegicus*) tissue. Samples were collected over eight days, at a 48-hour sampling interval. Soft tissue samples were extracted using Chelex-based methods and quantified using real-time Polymerase Chain Reaction (PCR) quantitation with a rat-specific target. DNA quantities decreased as the sampling interval increased for both maggot-fed and control tissues. No statistically significant difference in DNA recovery was observed for maggot-fed versus control tissues; however, statistically significant differences were observed for DNA quantities when comparing sampling intervals.

This presentation will discuss key findings related to sampling from maggot-fed soft tissues, the optimal time points for tissue sampling from decomposing tissue, and DNA recovery success over time.

B159 Why Mutation Models Matter: Enhancing Accuracy in Relationship Testing

Sanne E. Aalbers, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Katherine B. Gettings, PhD, National Institute of Standards & Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will feel knowledgeable about the mutation models available to them when performing relationship testing in forensic Short Tandem Repeat (STR) casework and will be able to describe differences between various mutation modeling approaches and their impact on the calculations. With this knowledge, attendees will be able to critically evaluate the mutation methods implemented in their laboratory protocols.

Impact Statement: This presentation impacts the forensic science community by highlighting the importance of considering mutations in STR casework and selecting appropriate models when performing relationship testing. By providing attendees with a deeper understanding of mutation modeling and their impact on the calculations, they will be able to accurately interpret relationship testing results, thereby improving the reliability and trustworthiness of forensic science outcomes.

Abstract Text: Relationship testing plays a critical role in resolving complex identification issues in various fields, including paternity testing, missing person investigations, and disaster victim identification. As comparisons are made between STR profiles of potentially close relatives, calculations rely on genetic inheritance patterns. However, the presence of mutations can complicate these analyses, leading to potential false exclusions when genetic changes are transmitted to the next generation. When potential genetic inconsistencies are observed, the possibility of mutation needs to be considered in the reported statistical calculation. Our work aims to analyze the performance of different mutation models to ensure accurate relationship testing results.

The Association for the Advancement of Blood & Biotherapies (AABB) collects and reports statistics from relationship testing laboratories in their yearly technical reports, including information on mutation calculation methods and locus- and sex-specific mutation rate data, and has published standards to improve the quality of relationship testing.[1,2] The Paternity Testing Committee of the International Society of Forensic Genetics (ISFG) has also published specific recommendations for paternity testing.[3,4] While there is agreement on the need to account for mutations in relationship testing in cases of genetic inconsistencies, the lack of a standardized approach to modeling mutations can lead to inconsistent results. Here, we investigate the impact of various mutation models on statistical calculations for relationship testing.

We simulated autosomal STR profiles for true paternity trios with an inconsistent locus and calculated the Paternity Index (PI) using different approaches for handling mutations. The methods evaluated include substituting the PI with the mutation rate and the mutation rate divided by the probability of exclusion, an approach that is used by about half of the AABB-reporting laboratories.[1] Other approaches included in this study adhere to Likelihood Ratio (LR) -based models, which are recommended by ISFG [4] and can account for STR repeat differences, such as the stepwise mutation model.[4,5]

We show that different mutation models can yield significantly different PI values, with greater discrepancies observed at high polymorphic markers (e.g., D12S391) compared to less polymorphic markers (e.g., TH01). Approaches that are not based on an LR generally provide lower PI values, while LR-based methods show more moderate values. Results are highly dependent on the accuracy of available mutation rate data.

Since different mutation models lead to differences in statistical output, it is important to carefully consider the mutation modeling approach in relationship testing, particularly in case of genetic inconsistencies. We recommend that laboratories consider the implications of different mutation models when validating their relationship testing protocols, which can be facilitated by available software such as Familias.[6] This study underscores the importance of a thorough understanding of the underlying principles and methods in relationship testing and the need for a nuanced approach to interpreting complex genetic data.

B160 Missing Person Identification: Anthropologic and Genetic Analyses of the Remains of the Fourth Victim of a Serial Killer in Southwest Ghana

Kofi Adjapong Afrifah, APM, Bowie State University, Bowie, MD*

Learning Objectives: Attendees will learn an optimized DNA extraction procedure for extracting DNA from degraded evidence such as human remains. This case highlights the importance of interdisciplinary approach to forensic investigations.

Impact Statement: This case highlights the importance of establishing regional genetic databases and strengthening the capacity of forensic scientists in West Africa. This case also provides a template for future efforts aimed at identifying human remains in Ghana and West Africa.

Abstract Text: The identification of human remains in criminal investigations may require interdisciplinary approach that integrates forensic anthropology and genetic analysis. We report on the anthropologic and molecular characterization of skeletal remains recovered in Southwest Ghana in 2019, later identified to be the fourth victim of a serial killer active between 2018 and 2020. Osteological examination included an inventory of skeletal remains, estimation of biological profile (age at death, sex, stature, and ancestry), and assessment of taphonomic alterations. Notably, epiphyseal fusion and dental wear patterns suggested a teenage (14–19 years) individual, while cranial morphology indicated female sex. Metric analysis of long bones estimated stature at 156–164 cm, which aligns with regional population data.

Genomic DNA was extracted from the skull using a silica-based protocol optimized for degraded samples. Short Tandem Repeat (STR) profiling yielded a complete autosomal profile, which was cross-referenced against a database established for relatives of missing persons. The remains were thus handed over to the relatives for final funeral rites and burial to bring closure to the long search for the victims of this serial killer.[1,2]

The use of anthropologic parameters and STR/maternal lineage data underscores the importance of interdisciplinary approach in resource-limited investigative departments in cities, counties and states.

B162 A Computer Interpretation of RapidHIT Mixtures for DNA Match Information

Paul Berry, MS, Louisiana State Police Crime Lab, Baton Rouge, LA; Baron Andrus, MS, Louisiana State Police Crime Laboratory, Baton Rouge, LA; Mark W. Perlin, MD, PhD*, Cybergenetics, Pittsburgh, PA; William P. Allan, MS, Cybergenetics, Pittsburgh, PA*

Learning Objectives: The RapidHIT instrument facilitates rapid genotyping of evidentiary samples, providing timely investigative leads. However, its limitations present challenges in the interpretation of DNA mixtures. When used in conjunction with TrueAllele probabilistic genotyping software, statistical weight can be assigned to potential matches, offering scientifically supported match probabilities even for complex or low-level DNA profiles generated by the RapidHIT ID system.

Impact Statement: This presentation will enhance the forensic science community's understanding of how the integration of RapidHIT technology with TrueAllele probabilistic genotyping software can improve the interpretation of complex Rapid DNA results. While RapidHIT provides fast genotyping from evidentiary samples, its limitations in mixture resolution or low-level single source profiles can hinder effective analysis. By incorporating TrueAllele's statistical approach to mixture deconvolution and match probability calculation, forensic practitioners can make more informed, scientifically defensible decisions in time-sensitive situations.

Abstract Text: RapidHIT ID is a Rapid DNA technology. The instrument transforms input DNA into Short Tandem Repeat (STR) data in about 1.5 hours. Rapid machines were originally intended for suspect identification from saliva reference samples in police stations. Technology advancements have expanded Rapid's scope to less pristine DNA items.[1]

Most DNA evidence is a mixture of two or more people. STR mixture data are often difficult to interpret by conventional human or computer review, due to allele overlap and Polymerase Chain Reaction (PCR) allele artifacts such as stutter, imbalance, and dropout. Mixtures can be highly probative, particularly when they place multiple people together at a crime scene. While DNA laboratory protocols can mitigate PCR artifacts, Rapid technology often cannot. Rapid's heterozygote allele imbalance may exceed 40%, showing pronounced allele dropout.[1] Indeed, Rapid ID can signal PCR stochastic effects (STO flag). The Louisiana State Police (LSP) finds human review of Rapid data unsuitable for DNA mixtures, determining them to be uninterpretable.

Cybergenetics invented TrueAllele Probabilistic Genotyping (PG) 25 years ago.[2] The technology uses Bayesian probability to mathematically separate genotypes from DNA mixture data, one for each contributor. Comparing separated probabilistic genotypes produces a reliable Likelihood Ratio (LR) match statistic that measures DNA association strength.[3] The LSP uses TrueAllele for DNA mixture interpretation.[4]

The LSP designed a DNA validation study to assess Rapid ID on single-source and two-person mixtures. The mixture ratios were roughly 1:9 (10%), 1:4 (20%), and (1:1) 50%. The laboratory used saliva samples from known individuals to synthesize the mixtures. Two swab types were compared, cotton and flocked.

LSP tested the DNA using RapidINTEL Plus Sample Cartridges containing 21 autosomal STR loci. The "General" protocol was applied to cotton swabs, and "Specialized" (low-template) to flocked swabs. Three different Rapid machines were used, producing triplicate data for each mixture condition. Stochastic PCR variation was observed on both single-source and mixture STR data.

Cybergenetics ran TrueAllele on the Rapid mixture data. Using short triplicate computer runs (5,000 MCMC readout cycles each), a swab's total interpretation time was about 30 minutes. The major contributor was easily identified, with log(LR) match information generally at 25 ban. The 10% to 20% minor components averaged around 15 ban. Minor components of 1% to 5% yielded around 5 ban. The Specialized-flocked protocol was more informative with extremely low mixture amounts.

Our study showed that TrueAllele interpretation of Rapid ID two-person saliva mixtures was fast and informative. No instrument or cartridge calibration was needed, since TrueAllele models the PCR experiment directly from the sample's STR evidence data. These results demonstrate the potential for timely and highly informative Rapid analysis of DNA mixtures.

B163 Rapid DNA Identification of Human Remains in Diverse Conditions: What Works, What Doesn't

Kayli N. Carrillo, BS, Sam Houston State University, El Paso, TX; Sheree R. Hughes, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will understand the RapidHIT ID (RHID) instrument's operational workflow and learn how to prioritize sample types most likely to yield successful results in Disaster Victim Identification (DVI) scenarios.

Impact Statement: This presentation will impact the forensic science community by demonstrating the effectiveness of the RHID system with RapidINTEL PLUS sample cartridges for processing human cadaveric samples while also describing which pretreatment methods for bone samples lead to improved Short Tandem Repeat (STR) profile completeness in DVI cases.

Abstract Text: Interest in rapid DNA has grown, especially since the Federal Bureau of Investigation (FBI) approved the upload of rapid DNA profiles into the Combined DNA Index System (CODIS).[1] Traditional DNA processing is now streamlined into an automated 90-minute process.[2] Law enforcement, medical examiners, and laboratories are using rapid DNA to develop investigative leads, identify and eliminate suspects, confirm familial relationships, and identify human remains.[3-5]

Thermo Fisher Scientific has developed the Applied Biosystems RapidINTEL PLUS Sample Cartridge to process more challenging samples.[6] This cartridge incorporates internal quality controls to flag inhibited, low-quantity, mixed, and/or degraded samples as well as quantification markers, to comply with FBI QAS 9.4 standards. Further research is needed to assess its effectiveness with sample types relevant to DVI scenarios, including bone, nails, and decomposed soft tissues.

This study evaluated optimal bone preparation methods for the RHID system by comparing different bone amounts and fragment sizes, including chips, powder, and spice ground fragments. Three different pretreatment lysis buffers were also tested (25% Prep-n-Go, PrepFiler BTA, and complete demineralization buffer). To evaluate these parameters, a modified off-line "Mock Rapid CE" protocol was employed to simulate the RHID process and serve as a triage step for identifying samples most suitable for rapid analysis. Following a two hour lysis, lysates were collected, supplemented with 100 µL of Prep-n-Go buffer, and incubated with the same parameters of the RHID system. After the second incubation, samples were quantified using the Quantifiler Trio kit and then Polymerase Chain Reaction (PCR) amplified with the GlobalFiler Express Kit. Amplified products were processed on the 3500 Genetic Analyzer.

Additionally, hair, fingernails, toenails, deltoid, and rectus femoris muscle samples were collected from three cadavers at various stages of decomposition (early decomposition, bloat, and advanced decomposition). These samples were assessed using rapid DNA analysis, and the results were compared with those from a traditional Capillary Electrophoresis (CE) workflow to determine when conventional methods are more appropriate than rapid DNA analysis. Profile completeness, concordance to reference profiles, peak height ratios, and quality control flags were evaluated to assess the performance of the RapidINTEL PLUS cartridge.

Results indicate that highly compromised bones are best processed with traditional methods as pretreatments did not improve rapid DNA results. However, early decomposed bones generated near-complete profiles. If a pretreatment was chosen, 25% Prep-n-Go would be the easiest to implement while obtaining full profiles. Additionally, spice-ground fragments were shown to be a suitable preparation method for rapid processing. Among the cadaveric samples, early decomposed nails and muscles provided the most reliable results, while advanced decomposed muscle, hair, and nails did not yield CODIS-eligible profiles for missing persons and should be processed with traditional CE analysis. The findings of this research provide guidance for medical examiners, law enforcement, and laboratories using rapid DNA to process human remains under diverse conditions.

B164 An Evaluation of Compromised Teeth Using an Optimized Sample Preparation Method and the Applied Biosystems RapidHIT ID System

Tracey Dawson Green, PhD, Department of Forensic Science, Virginia Commonwealth University, Richmond, VA; Raygan Harrington, MScFS, Virginia Commonwealth University, Richmond, VA; Yen H. Dang, MScFS, Santa Cruz County Sheriff's Office, Morgan Hill, CA; Ali Mojarad, DDS, Virginia Commonwealth University, Department of Periodontics, Richmond, VA; Janina Golob Deeb, DDS, Virginia Commonwealth University, Richmond, VA; Morgan E. Eaton, MScFS, Colorado Bureau of Investigation, Grand Junction, CO*

Learning Objectives: This presentation will provide attendees the knowledge to understand some of the challenges posed when using teeth as samples for DNA profiling—especially in situations of disaster victim identification—along with the impact of these challenges to the overall Short Tandem Repeat (STR) profile quality when using a RapidHIT ID System.

Impact Statement: This presentation will impact the forensic science community by demonstrating that teeth are viable samples for DNA profiling for disaster victim identification when more traditional samples are not available. In addition, the data suggests that whole tooth processing produces higher quality results than fragmented or pulverized samples, contradicting previous ideologies regarding hard tissue samples. Utilizing whole tooth samples alongside the RapidHIT ID System could drastically reduce the overall time spent developing STR profiles without compromising on profile quality.

Abstract Text: DNA profiles are often generated from high-quality samples such as blood and saliva; however, these sample types are not always available, especially following mass disasters.[1] Bones and teeth are common secondary sources, although there are several downfalls when using these samples. Perhaps the most prominent is the time and labor it takes to prepare these samples for the forensic DNA workflow. Additionally, when considering teeth over bone, scientists may not be sure of which teeth to look for or how different conditions may affect the quality.[2] This research aims to answer these questions by using an optimized protocol specifically designed for teeth samples to be processed using the Applied Biosystems RapidHIT ID System. The system is able to produce a DNA profile in approximately 90 minutes, in comparison to the traditional workflow, which can take days to months.[3]

For this study, 115 compromised teeth were collected and separated into four challenge groups. The teeth were cleaned following an optimized sample preparation protocol. In order to ensure that they fit in the RapidINTEL cartridge, teeth larger than 6mm at the widest point were fragmented using a hammer. For all samples, the general RapidHIT protocol was used.

The results demonstrated that 11% of all compromised teeth generated profiles that passed the automated analysis without analyst review and were immediately available for searching in the accompanying software. The rate of first pass samples was then compared across the various challenge groups. The total number of incisor samples that immediately passed was significantly higher than the number of molars. Overall, smaller teeth had an increased probability of providing passing STR profiles without analyst review. A significantly higher number of teeth impacted with caries produced STR profiles that passed with automated analysis compared to those that were healthy and those impacted with common pathologies or treatments. Additionally, there was a moderately positive correlation between the time a sample was stored and the amount of DNA amplified (R2=0.4533). Further, there was a weak negative correlation between storage time and number of artifacts observed (R2=0.1165). No correlation was found between donor age and any of the quality metrics analyzed. There were also no significant differences found between the tooth type and profile quality indicators. Larger teeth, which were more likely to need fragmentation, produced more artifacts per sample. Teeth impacted with caries produced significantly more amplified DNA than healthy teeth. Lastly, root canal-treated teeth were more likely to produce STR profiles with artifacts present.

The data demonstrates that compromised teeth can be used as viable samples for STR profile analysis using the RapidHIT ID System, regardless of short-term storage length, donor age, tooth type, or common pathologies and treatments. However, if these samples were to be processed on scene, a trained DNA analyst would need to be present to review the samples that do not pass with automated analysis. Additionally, in a laboratory setting, the STR profiles developed proved to be manageable and useful, providing high-quality results quickly with minimal labor.

B165 Forensic Science Bias Against the Wrongfully Accused: Sperm Fractions, Defense Hypotheses, Screening Tests, and the Absence of Evidence—Lessons From Exonerations

Greg Hampikian, PhD, CompGenomics, Boise, ID*

Learning Objectives: Participants will learn to recognize and appreciate biasing terminology, inferences, and methodologies. Terms such Absence of Evidence, Sperm Fraction, Blood Spot (based on screening test), Defense Hypothesis, Touch DNA, Inconclusive, Can Not Exclude, Insufficient Male DNA, Weak Positive, and 1+ (sperm "counts" without photos) will be discussed with case examples from trials and exonerations.

Impact Statement: Wrongful convictions and exonerations have shown how standard lab practices can lead to tragic outcomes. The challenge for forensic practitioners, and all who serve in the justice system, is to identify current practices that could bias outcomes. Many of these biases have evolved from the noble goals of the justice system: keep the public safe and "get the right guy." Identifying current bias requires a mindset that considers the wrongfully accused, who are the victims of the system itself. By examining forensic practices and terminology from the perspective of the wrongfully accused, practitioners will be prepared to face the challenge of removing bias from their practices.

Abstract Text: Imagine that a loved one is wrongfully accused of a terrible crime. Their hope lies in the forensic science. Yet forensic science has played a part in hundreds of wrongful convictions. This presentation will share examples from trials and exonerations where ambiguous, misleading, or incorrect forensic science was used. Jurors and judges are the ultimate "customers" of forensic services, and the ones who must weigh the evidence with the help of expert testimony.

A challenge for forensic professionals is to produce and communicate results in a neutral manner. This includes proper documentation of all subjective findings (micrographs of sperm cells, photos of colorimetric serology tests, etc.) that can be reviewed by other experts at any time. It also requires continuous monitoring of language that unintentionally biases findings. Examples of potentially biasing language include categorizing stains based on screening tests, for example calling a stain blood or semen without a confirmatory test, the use of terms such as "defense hypothesis" (without consultation of the defense), and the false aphorism "the absence of evidence is not the evidence of absence." The extreme variance of statistical match frequencies produced by various approaches, the need for validated limits for every test, and the responsibility to represent the literature of the field (rather than one's limited experience) will also be discussed.[1]

B166 The Current Landscape of Forensic Genetic Genealogy Implementation, Understanding, and Opinions in the United States

Julia M. Otto, Villanova University, Watertown, MN; Melanie T. Armstrong, BA, ThroughLine Consultants, Vienna, VA; Tynan Peterson, MA, ThroughLine Consultants, Oakland, CA; Megan M. Foley, PhD, Hamline University, St. Paul, MN*

Learning Objectives: After attending this presentation, attendees will better understand the current landscape of Forensic Genetic Genealogy (FGG) in the United States, including how laboratories are engaging with FGG, the tools and workflows in use, and conditions and standards guiding current and future application to criminal investigations based on a survey of professionals in the related fields. Opinions of DNA analysts and genealogists regarding education, training, and standardization of both the DNA processing and genealogy investigation work will be discussed.

Impact Statement: This presentation will impact the forensic science community by identifying gaps in current understanding, resources, training, and standardization and by informing the development of best practices and policy recommendations to support the responsible use of FGG in casework.

Abstract Text: FGG has emerged as a powerful interdisciplinary tool that merges forensic DNA analysis with genealogical research. Officially recognized in 2018 through its high-profile role in solving the Golden State Killer case, FGG has since become instrumental in resolving cold cases, identifying human remains, and advancing investigations where conventional methods have stalled.[1,2] Unlike traditional forensic DNA profiling, which relies on 13–20 Short Tandem Repeat (STR) markers compared against the Combined DNA Index System (CODIS), FGG uses high-density Single Nucleotide Polymorphism (SNP) profiling, often analyzing 600,000 to 1,000,000 markers, and compares these profiles to consumer genetic genealogy databases.[3] This research draws on a survey-based study of members of the American Academy of Forensic Sciences (AAFS), focusing on professionals in forensic biology and genetic genealogy in the United States. The survey evaluated current practices, institutional policies, and professional opinions regarding FGG implementation and oversight. Synthesizing responses provides insight into the operational landscape of FGG, identifies gaps in standardization, and highlights opportunities to advance methodological consistency and ethical accountability.[4,5]

A total of 99 responses were received, representing at least 34 United States states and territories. More than 50% of respondents primarily perform traditional DNA casework, while about 6% currently process DNA for FGG or perform FGG analysis. Around 45% reported working in laboratories that neither process DNA for FGG nor perform FGG analysis. Among organizations not performing FGG (~50 respondents), 28% are considering or planning to implement it, 20% do not plan to, 30% reported it is not on their radar, and the remaining were unsure. Reasons cited for non-implementation include limited resources, preference for outsourcing, waiting for clearer standards, or viewing it as not adding value. About 50% of respondents are aware of initiatives to develop standards for processing DNA profiles for FGG. Similar levels of awareness were reported for standards guiding FGG analysis itself. Nearly 90% believe laboratories generating FGG profiles should follow the same guidelines as traditional DNA labs, though support for applying those same standards to organizations performing FGG drops to about 70%.

Overall, these results reveal a field in transition. Interest in FGG is growing, but variability in implementation, awareness, and standardization remains. Continued collaboration, training, and clear policy development will be critical to ensuring FGG's responsible and effective integration into forensic practice.

B167 How Should We Report Genetic Matches Following an Investigative Genetic Genealogy Search?

Feriel Ouerghi, BS, Quantitative and Computarional Biology, Los Angeles, CA; Michael D. Edge, PhD, University of Southern California, Los Angeles, CA; Dan E. Krane, PhD, Wright State University, Dayton, OH*

Learning Objectives: Attendees will learn how identification through Forensic Investigative Genetic Genealogy (FIGG) can influence Short Tandem Repeat (STR) match statistics when the additional genetic information inherent to the FIGG process is not accounted for.

Impact Statement: This presentation will affect the forensic science community by proposing a conservative framework for interpreting STR match statistics in cases involving FIGG.

Abstract Text: Traditional forensic genetics practice in the United States has historically relied on STR analysis for DNA profiling, as implemented in the Combined DNA Index System (CODIS). One widely used statistic for summarizing the evidence provided by a match between STR genotypes is the Random Match Probability (RMP), the estimated probability that a random person would produce an STR profile matching a forensic sample. Over the past decade, a new approach called FIGG has been instrumental in solving hundreds of criminal cases. FIGG differs from standard forensic-genetic practice in that it is based on inferences of genealogical relatedness from genome-wide SNPs rather than matching at STR loci. Currently, suspects identified through FIGG are genotyped at CODIS (STR) markers, and a summary of the evidence from the match—such as an RMP—is subsequently reported in court. However, the calculated STR match statistics do not account for the fact that the suspect was initially identified through a FIGG match, which itself provides additional genetic evidence.

Using both forward and coalescent population-genetic simulations, we explore the effect of identical-by-descent segments shared among relatives on STR match statistics, as well as the impact of population structure and assortative mating. We quantify the extent to which these phenomena bias reported match statistics and develop recommendations for conservatively reporting them following identification via FIGG.

B168 When Science Speaks for the Dead: A Multi-Collaboration for Human Remains Identification

Lisa Mertz, MS, Office of Chief Medical Examiner, NYC, New York, NY; Karen L. Ross, JD*, Queens District Attorney Office, New York, NY*

Learning Objectives: Three critical learning objectives will be discussed with the attendees in this presentation: (1) No case is too old to pursue—as forensic technology continues to advance, every unidentified victim deserves the chance to be named; (2) Collaboration is essential—partnerships between law enforcement, prosecutors, forensic scientists, genealogists, and families are vital to solving cold cases; and (3) The human impact cannot be overstated—while the work is scientific and procedural, its consequences are profoundly personal for the families involved.

Impact Statement: In this presentation, attendees will learn how advances in forensic science are transforming the identification of long-unidentified human remains and delivering answers and long-awaited justice to families. This session will explore the application of DNA testing and the Combined DNA Index System (CODIS) entry, the integration of forensic genetic genealogy, forensic facial approximation, case cataloging and management, and best practices for multi-agency collaboration.

Abstract Text: Each year, thousands of human remains cases remain unidentified and countless cold cases go unsolved. These unresolved cases leave families in anguish, communities unsettled, and justice incomplete. Identifying human remains is more than a scientific challenge—it restores dignity to the deceased and brings long-sought answers to loved ones. Yet the obstacles are considerable: decades-old evidence, degraded or limited DNA samples, and constrained resources often impede resolution. This presentation will highlight how innovations in forensic science, combined with strategic, cross-agency collaboration are essential to breaking these barriers.

We will outline a practical, collaborative framework for addressing backlogs of unidentified remains, emphasizing modern forensic techniques, strategic case management, and interagency partnerships. Topics will include the integration of forensic genetic genealogy, the use of forensic facial approximation photographs for public appeals, and effective protocols for prioritizing, cataloging and managing unidentified remains cases.

We will detail the successful collaboration between Queens District Attorney's Office and the New York City Office of Chief Medical Examiner, illustrating how multidisciplinary coordination among prosecutors, law enforcement, forensic scientists, and genealogists is critical to success. The presentation will emphasize the importance of prioritizing cases, securing and sharing data, and communicating findings effectively to resolve longstanding investigations.

This presentation offers a proven, replicable roadmap for jurisdictions seeking to modernize their cold case workflows and address the backlog of unidentified remains. It will encourage and inspire the forensic and legal communities to continue this vital work—restoring names, delivering justice, and providing answers that families have waited for far too long.

B169 Solving Complex DNA Mixtures With Next Generation Sequencing

Kari Danser, MS, Cybergenetics, Pittsburgh, PA; William P. Allan, MS, Cybergenetics, Pittsburgh, PA; Mark W. Perlin, MD, PhD*, Cybergenetics, Pittsburgh, PA*

Learning Objectives: After attending this presentation, attendees will understand how combining Next Generation Sequencing (NGS) with Probabilistic Genotyping (PG) solves complex DNA mixtures that traditional methods cannot interpret. Participants will learn how to combine NGS with PG to solve cold cases, identify unknown contributors, and advance forensic capabilities.

Impact Statement: This presentation will improve the forensic community's ability to interpret complex DNA mixtures by applying PG interpretation to NGS data. Practitioners can use this new capability on real-world casework to better resolve challenging DNA evidence. They can combine NGS with PG to obtain more accurate identifications for stronger case outcomes.

Abstract Text: NGS represents a transformative leap in forensic science. It generates massively parallel DNA data from degraded or low-level samples, opening new paths to solve previously unsolvable cases. When paired with advanced probabilistic genotyping, forensic experts can separate complex mixtures, extract meaningful profiles from challenging evidence, and quantify results with unparalleled precision. These innovations redefine what forensic science can achieve in casework, victim identification, and criminal investigations.

We present the *Ohio v. Slater Howell* case alongside Short Tandem Repeat (STR) data from an NGS validation study. In April 2014, gas station clerk Babul Saha was fatally shot during a Cleveland robbery. Investigators collected DNA from the gas pump button, a plastic bag, and a lottery register. Promega PowerPlex Fusion amplified 22 STR loci. The bag data showed a complex seven-person mixture that the crime laboratory could not interpret using manual Combined Probability of Inclusion (CPI) methods.

TrueAllele PG analysis fully resolved these Capillary Electrophoresis (CE) mixtures.[1-3] The computer linked Slater Howell to the crime. But how would the analysis have looked had NGS data been used?

We retraced the case's PG analysis steps using NGS mixture validation data in place of the original CE data. The validation study had analyzed 251 total samples of different mixture compositions, plus single source and mock casework items. The study generated NGS data with Verogen ForenSeq DNA Signature at 27 STR loci.

We assembled seven-person mock mixture data from three NGS validation samples of known composition. We combined the three read spreadsheets into one read spreadsheet to use as casework mixture data. The suspect and victim mixture weights were comparable those found in the *Howell* CE bag evidence. We entered this NGS data into TrueAllele.

TrueAllele computationally separated the complex NGS mixture bag data into seven genotypes, up to probability. The software then compared these evidence genotypes with known suspect and victim references. TrueAllele calculated log (Likelihood Ratio [LR]) values between evidence and reference on both the CE and NGS data.

On the original CE case data, the reported log (LR) was 4.99 ban for the suspect and 5.35 ban for the victim. On the NGS data, TrueAllele found 7.74 suspect and 8.61 victim log (LR) scores. The NGS information increase was largely due to having five additional STR loci. Using TrueAllele, the mock NGS results paralleled the CE casework results.

NGS has not yet gained widespread adoption for DNA analysis in the forensic science community. A key reason has been the lack of powerful NGS data interpretation software that can extract useful information from the complex DNA mixtures seen in everyday casework. While NGS may offer better data, PG software can solve CE data.

However, combining better NGS data with PG software gives the best of both worlds. NGS improves on CE, and PG improves on CPI. Together, NGS plus PG provides a synergistic solution. As demonstrated here, coupling NGS with powerful software that unmixes DNA mixtures offers new solutions to challenging DNA evidence problems.

B170 The Developmental Validation of Software for Deconvolution of Mixed mtDNA Samples

Brian Young, PhD, NicheVision Forensics, Akron, OH; Tom Faris, BSc, NicheVision Forensics, Akron, OH*

Learning Objectives: Attendees will learn the principles of mixture deconvolution of mixed mitochondrial DNA (mtDNA) samples. Attendees will be introduced to phylogenetic mtDNA analysis and probabilistic analysis via the expectation maximization algorithm.[1,2]

Impact Statement: The technology presented here will enable the use of mtDNA in casework samples for familial analysis or matching. In addition, an empirical estimate of the number of non-maternally related contributors to samples is generated and can be applied to Short Tandem Repeat (STR) analysis of the same samples.

Abstract Text: mtDNA has traditionally been analyzed using Sanger sequencing on single-source samples in scenarios where insufficient DNA is available for nuclear DNA analysis. Massively Parallel Sequencing (MPS) enables analysis of mixed mtDNA [3] and provides the potential to address two current needs in forensic DNA analysis: (1) deriving familial evidence from casework samples, and (2) estimating the number of contributors to DNA mixtures.[3,4] However, validated software for mixed mtDNA analysis has not been available.

We present validation results for the MixtureAceMT software. MixtureAceMT accepts data from forensic Polymerase Chain Reaction (PCR) kits covering the control region only, or the entire mtDNA chromosome.[5] Shotgun sequencing is also accepted. Data files can be pre-processed by filtering for Nuclear Mitochondrial DNA Segments (NUMTs), correcting for sequencing errors, filtering on base call or mapping quality, and trimming primer sequences (if present). MixtureAceMT software uses a phylogenetically aware probabilistic approach to classify individual sequencing reads in FASTQ or BAM data files. Expectation maximization in the underlying MIXEMT algorithm yields Maximum Likelihood Estimates (MLE) of the proportion ratios of contributors to mixtures, along with their haplogroups.[6] Contributor haplogroups are indicative of biogeographic ancestry. Haplotypes and assembled sequences (partial or full) are also reported for each contributor. Contributor haplotype calls can be used for familial matching. The estimated number of haplogroups provides an empirical estimate of the number of non-maternally related individuals in the mixture. The called haplotypes further refine this estimate. Performance results of key functional requirements will be presented along with results of accuracy and precision testing.

B171 The Development and Evaluation of a Phase Analysis Pathway for mtDNA Mixture Deconvolution

Zack Beyerl, MFS, Bode Technology, Washington, DC; Robert Lagacé, BA, Thermo Fisher Scientific, Pleasanton, CA; Daniele S. Podini, PhD, The George Washington University, Washington, DC*

Learning Objectives: By attending this presentation, participants will learn about a simple bioinformatic pipeline that allows for straightforward analysis of phased mitochondrial DNA (mtDNA) haplotypes and how it can be used to more reliably deconvolute mtDNA mixtures.

Impact Statement: Mixtures in mtDNA analysis are particularly complex, as they can originate from both intra-individual variation (heteroplasmy) and contributions from multiple individuals. Despite advancements in mtDNA analysis, most laboratories still consider such mixtures uninterpretable. This study demonstrates how a customized bioinformatic pipeline for simple phase analysis of mtDNA haplotypes can significantly improve mtDNA mixture interpretation accuracy and expand the range of mtDNA mixtures suitable for deconvolution.

Abstract Text: mtDNA mixture samples can be present in samples from a variety of sources including heteroplasmy, Nuclear Mitochondrial DNA Segments (NUMTs), or simply by there being multiple contributors. Heteroplasmy, in some cases, can increase the power of discrimination of mtDNA, while NUMTs and contamination represent two of the bigger challenges for mtDNA analysis.[1,2] Beyond identifying the presence of a mixture or classifying it as heteroplasmy, little progress has been made in effectively deconvoluting mitochondrial DNA mixtures to resolve and identify the individual haplotypes of different contributors. This is largely due to the non-quantitative nature of the traditional Sanger Type Sequencing, which prevents accurate Single Nucleotide Polymorphisms (SNP) phasing necessary for haplotype determination. With the popularization of massively parallel sequencing, mtDNA mixtures have received increased attention.[3] The currently developed methods use sequencing coverage and phylogeny as the focus of their deconvolution efforts, which can result in issues with contributors of similar proportions and private mutations, respectively.[4,5] Mitochondrial Mixture Deconvolution and Interpretation Tool (MMDIT) is one such mixture interpretation tool built on sequencing coverage and is the only mtDNA mixture deconvolution tool to deconvolute into haplotypes instead of haplogroups, but it can have issues with overly balanced or imbalanced mixtures.[5]

To address these limitations, this study explored whether phase analysis—examining the full length of sequencing reads to assess linked nucleotides—could be applied to mitochondrial DNA mixture deconvolution and aimed to develop an interpretation framework based on this approach. The pathway utilizes a set of tools (mito-variant caller, mh.jar, and an in-house variant caller) to phylogenetically align, phase, and variant call mtDNA mixtures, which allows for both physical and phylogenetic deconvolution to be performed.[6] To evaluate the effectiveness of the developed interpretation pathway and guidelines, a set of 30 mixtures, comprising two- and three-person contributors, were simulated using samples previously typed with the Precision ID mtDNA Control Panel. Mixtures were simulated by randomly subsampling reads of the previously typed single-source samples to create mixtures with the desired proportions. These mixtures were analyzed using both the developed pathway and MMDIT to test the deconvolution ability of the phase pathway. The phase pathway showed a considerable increase in deconvolution ability over MMDIT, especially in unbalanced mixtures. Twenty-seven of the tested mixtures had inclusions of all of the true contributors using phase analysis while only 11 were included for MMDIT. Additionally, the major contributor was only correctly called in one of the 11 mixtures for MMDIT while for phase analysis, the correct major contributor was called in all mixtures, including mixtures where the minor contributors were excluded.

Limitations such as heteroplasmic contributors and maternally related individuals in mixtures are intrinsic issues that affect accurate deconvolution of affected mtDNA mixtures and are not addressed with this pathway. Despite current limitations and the need for manual interpretation, this approach shows promising advancements and establishes a foundation for the future development of a probabilistic genotyping tool based on phase analysis.

B172 An Evaluation of a qPCR-Based Normalization Strategy to Improve Sample-to-Sample Read Depth Balance in STR Libraries Generated Using the IDseek CombiSTR Plus Reverse Complement PCR Technology

Eleanor Starkey, BS, Thomas Jefferson University, Horsham, PA; Coral M. Smith, MS, CFSRE, Horsham, PA; Jill van Wolferen, MSc, NimaGen BV, Nijmegen, Gelderland, Netherlands; Joop P.G. Theelen, BASc, NimaGen B.V., Nijmegen, Gelderland, Netherlands; Mirna Ghemrawi, PhD, The Center for Forensic Science Research and Eduction, Horsham, PA*

Learning Objectives: Attendees will gain an understanding of how library normalization strategies affect the quality and consistency of Short Tandem Repeat (STR) data generated through Massively Parallel Sequencing (MPS). By comparing a quantitative Polymerase Chain Reaction (qPCR) -based normalization approach to the traditional input-based method, this presentation will highlight differences in sequencing balance, read depth, and allele recovery.

Impact Statement: This study highlights how qPCR-based normalization can improve sequencing balance and data consistency in forensic STR analysis using MPS. The results support its potential to enhance the reliability of STR sequencing and streamline forensic laboratory workflows.

Abstract Text: MPS-based STR typing has been proven to offer advantages over traditional capillary electrophoresis methods that include distinguishing isoalleles, improving mixture interpretation, and increasing multiplexing capacity.[1] The IDseek CombiSTR Plus library preparation assay, which uses Reverse Complement Polymerase Chain Reaction (RC-PCR) chemistry, enables simultaneous analysis of autosomal and Y-chromosomal Short Tandem Repeat (Y-STR) loci in a single workflow. RC-PCR is a novel library preparation technique in the forensic sequencing community that streamlines workflows by incorporating index and adapter sequences in a single, closed-tube PCR reaction, reducing contamination risk and hands-on time.[2] A critical component of the MPS workflow is sample normalization, which occurs after library prep and before pooling. Imbalanced inputs can lead to over- or under-representation of individual samples in the sequencing run, ultimately impacting data quality and profile recovery.

The current pooling scheme in the IDseek CombiSTR Plus library preparation workflow depends on the DNA quantity post-extraction (input-based). This approach does not account for the efficiency of the RC-PCR reaction, which can vary depending on sample type and quality. A novel qPCR-based normalization method has been introduced to quantify the amount of library available after RC-PCR, aiming to provide a more accurate and consistent pooling approach. This study evaluates whether qPCR-based normalization leads to improved sample-to-sample read depth balance and an increase in overall data quality compared to the traditional input-based method.

Following the Scientific Working Group on DNA Analysis Methods (SWGDAM) guidelines, a series of five studies involving a total of 62 samples run in triplicate (n = 186) were processed and analyzed using both normalization strategies.[3] These studies included sensitivity, stability, degradation, mixture, and case-type samples. Samples underwent DNA extraction, quantification, RC-PCR amplification, pooling, and cleanup before sequencing on the MiSeq FGx system. For data analysis and interpretation, a pairwise comparison of the two normalization methods was performed to evaluate read depth uniformity, locus balance, and dropout rates. Preliminary analysis demonstrates an improved sample-to-sample read depth using the qPCR approach. The findings may inform the best practices for library preparation and normalization in forensic MPS workflows, with potential implications for data consistency, interpretability, and operational efficiency in casework applications.

B173 A Forensic Quantification Kit for Human and Bacterial DNA Using Nanoplate Digital Polymerase Chain Reaction

Sylvia S. Etim, MS, Florida International University, Miami, FL; Bruce R. McCord, PhD, Florida International University, Miami, FL*

Learning Objectives: By the end of this presentation, attendees will be able to understand the development of a dual microbial and human forensic quantification kit using digital Polymerase Chain Reaction (PCR).

Impact Statement: This presentation discusses the impact of a generic microbial probe to a previously developed human DNA quantification system involving the detection of autosomal and mitochondrial DNA. The kit is aimed toward improving the quality of Next Generation Sequencing (NGS) results for human identification.

Abstract Text: NGS provides a high throughput and automated method for DNA typing, with applications that include autosomal and Y Short Tandem Repeats (STRs), as well as Single Nucleotide Polymorphismss (SNPs) and mitochondrial DNA (mtDNA) for ancestry and phenotyping. However, the quality results can be impacted through bacterial contamination. Excessive bacterial DNA in a sample can lead to spurious DNA sequences, erroneous readings, reference genome mis-mapping, and false alignments.[1]

Most commercially available real-time quantification kits detect and quantify human and Y chromosomal DNA as well as provide information on sample degradation and inhibition.[2] However, these kits do not include a bacterial quantification step. It was the goal of this project to add a generic bacterial probe to a digital PCR-based multiplex to address this situation.

As with real-time PCR, digital PCR instruments can be used to quantify and normalize the input level of human DNA prior to genotyping or sequencing. There are certain advantages to the use of digital PCR. This procedure permits direct detection and amplification of individual nucleic acid strands in nanowells as opposed to real time PCR which amplifies an entire sample in bulk. This technique improves specificity and sensitivity as well as adds inhibition resistance due to the advantages on endpoint quantitation. Ultimately, the number of copies is determined by counting the number of positive wells and applying a Poisson distribution to correct for wells containing more than one DNA copy. The instrument permits the simultaneous quantification of up to 12 dye-labeled amplicons, permitting autosomal, Y, mtDNA, and microbial probes to be detected simultaneously.

In this project, an existing DNA kit (Qiagen Investigator Quantiplex Pro) was modified to include an amplicon capable of detecting the presence of bacterial DNA in the sample.[3] This kit was validated by testing its capability to detect bacterial contamination by examining various spiked and simulated forensic samples, including both smoothed and roughened surfaces. The system was shown to be quite sensitive with the capability to detect bacterial DNA at levels as low as 10fg/ul.

Overall, we believe this new quantitative system should prove valuable for quantifying and triaging samples intended for NGS as well as electrophoresis-based analysis. Its improved sensitivity and resistance to PCR inhibition should also improve results with low-level and degraded samples.

B174 An Evaluation of the NexGenID Software for Complex Mixture Deconvolution Using Microhaplotypes

Lauren Borchert, BS, The George Washington University, Washington, DC; Sarah Cavanaugh, MSFS, Bode Technology, Lorton, VA; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Andrew B. Feldman, PhD, NexGen Forensic Sciences, Inc., Columbia, MD; Emily K. Kim, BS, The George Washington University, Washington, DC; Jeffrey Lin, MS, NexGen Forensic Sciences Inc., Silver Spring, MD*

Learning Objectives: After attending this presentation, attendees will learn about the deconvolution of complex mixtures using NexGenID, a new software that integrates bioinformatic analysis, mixture deconvolution, and probabilistic genotyping from Massively Parallel Sequencing (MPS) of microhaplotypes in how it functions as well as how to navigate the software and interpret the results.

Impact Statement: This presentation will impact the forensic science community by introducing NexGenID, a novel and accessible tool for forensic mixture deconvolution, designed to be integrated into routine casework. NexGenID is an all-in-one software that includes bioinformatic processing of FASTQ files followed by allele calling, mixture deconvolution, probabilistic genotyping of microhaplotype data, and database search.

Abstract Text: Complex mixture deconvolution is one of the most challenging tasks in forensic DNA casework. Issues such as allele dropout, allele sharing among contributors, and Polymerase Chain Reaction (PCR) artifacts (e.g., stutter) complicate interpretation and contribute to inter-analyst variability in determining the Number of Contributors (NoC).[1] Deconvolution may be improved by sequencing Microhaplotypes (MH) as they are not subject to the amplification noise artifacts and stochastic effects that impact Short Tandem Repeats (STRs).[2] Coupling a highly discriminatory MH Massively Parallel Sequencing (MPS) assay with NexGenID, a novel software platform optimized for mixture deconvolution and probabilistic genotyping of sequence data, addresses these challenges. This project assessed the ability of the NexGenID software to deconvolve complex mixtures and improve minor-contributor detection when compared to STR deconvolution using MPS data. For this project, a 43-locus panel of MH markers was constructed based on high effective number of Alleles (Ae) values as a predictor for their efficacy in mixture deconvolution. Mixtures were prepared with varying ratios, NoC, and input DNA amounts (0.5 ng, 1 ng, and 5 ng), and were target amplified with a custom MH assay and AmpliSeq for Illumina chemistry prior to MiSeq FGx platform. FASTQ files were analyzed using NexGenID, which aligns to locus references, conducts data quality assessment, clusters sequences into candidate alleles, matches to a known genotype database, conducts de novo resolution of contributor genotypes, and calculates Likelihood Ratios (LRs) and genotype matching confidence. Genotype weights for LR analysis are derived using an information theoretic framework with maximum likelihood estimation.[3] All sources of uncertainty and statistical variation are modeled from first principles based on the input DNA quantity specified by the analyst.

Preliminary findings indicate that mixtures containing 5 ng of input DNA produce the highest-confidence genotypes across all contributor scenarios as expected due to the lower effects of statistical sampling and measurement noise. Two- and three-person mixtures were accurately deconvoluted, with all contributors correctly identified. As expected, four-person mixtures showed a slight reduction in confidence—particularly for the lowest-level contributors—but still resulted in full contributor identification. Five-person mixtures presented the greatest challenges in resolving minor contributors (e.g., 61:24:10:4:1, or 36:34:24:4:2), occasionally not supporting the inclusion of the lowest contributor primarily as a consequence of drop out rather than software limitations. Processing time of the end-to-end analysis workflow ranges from approximately ~10 minutes for a two-person mixture to ~3 hours for a five-person mixture with a Windows 11 with Intel Core i7-14700 processor. For comparison, processing times for STR-based mixtures with the same NoC, analyzed using EuroForMix and STRmix on the same computer, are similar for less than four contributors, but STR mixtures of five contributors frequently resulted in software crashes. This presentation will include an expanded evaluation of NexGenID's performance across a broader range of mixture scenarios as well as a comparison with EuroForMix. Special emphasis will be placed on the interpretation and comparison of LR outputs, highlighting key differences and insights gained from the side-by-side analysis of the two software tools.

B175 Linkage Patterns of Forensically Relevant Identity SNPs and Autosomal STRs Commonly Multiplexed in Sequencing Assays

Isabella S. George, MFS, South Carolina Law Enforcement Division, West Columbia, SC; Megan M. Foley, PhD, Hamline University, St. Paul, MN; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Jamie L. Belrose, PhD, New York State Police, Albany, NY*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the genetic linkage between identity-informative Single Nucleotide Polymorphisms (SNPs) and autosomal Short Tandem Repeat (STR) markers in commercially available sequencing assays through the usage of genetic distances and linkage disequilibrium analysis.

Impact Statement: This presentation will allow practitioners in the forensic field to effectively utilize sequencing data in the courtroom. It will also encourage the development of improved statistical approaches for data interpretation that will fully leverage the genetic information made available by Massively Parallel Sequencing (MPS) technologies.

Abstract Text: The use of identity-informative SNPs (iiSNPs) alongside autosomal STRs has been found to be useful in forensic casework and paternity cases. The combination of STRs and iiSNPs have been analyzed to see how informative the combined marker types are as a panel in sequencing kits such as ForenSeq DNA Signature Prep (SigPrep) Kit and ThermoFisher Precision ID Panel.[1,2] Next Generation Sequencing (NGS), or MPS, has become increasingly popular for DNA typing because of its increased sensitivity, ability to simultaneously detect large numbers and types of markers, and its usefulness in detecting lower-level contributors in mixture samples.[3,4]

When analyzing and reporting on crime scene samples, statistical analysis is required when an association is made. The Federal Bureau of Investigation (FBI), along with the Scientific Working Group on DNA Analysis Methods (SWGDAM), have established the use of statistics in forensic casework in their *QAS (Quality Assurance Standards for Forensic DNA Testing Laboratories)* guidelines and *SWGDAM Interpretation Guidelines for Autosomal STR Typing by Forensic DNA Testing Laboratories*, respectively.[5,6] However, the proper statistical analysis using iiSNPs in sequencing-based kits has not yet been determined because linkage of current sequencing panels has not yet been extensively studied. Using genetic distance and Linkage Disequilibrium (LD) analyses to determine linkage between two markers, this research evaluated numerous instances of linked markers on each chromosome. The traditional 50cM (50% recombination rate) threshold was used to determine linkage for this research, as linked loci typically have a recombination frequency of less than 50% (7), but markers below the 30 cM and 40 cM thresholds were also identified. All chromosomes contain linked markers, ranging from two to six linked markers. All markers on five chromosomes were linked. Unlinked iiSNP markers generally had very low levels of LD while LD values of linked markers varied and did not follow a pattern. In addition, no meaningful difference was found in the number of linked markers under the 40 and 50 cM thresholds. However, less linked markers were observed under the 30 cM threshold. This research enhances our understanding of the linkage and association among markers included in current sequencing platforms such as the ForenSeq Signature Prep Kit and informs ongoing discussions regarding the most appropriate statistical approaches for their combined use in forensic analysis.

B176 The Identification and Optimization of MicroRNA Biomarkers for Predicting Body Weight and Muscularity in Forensic Samples

Xiaomeng (Simone) Yang, MS, Integrative Life Sciences PhD Program, Virginia Commonwealth University, Richmond, VA; Daja R. Bonilla, BSFS, Virginia Commonwealth University Forensic Science Department, Richmond, VA; Sarah Seashols-Williams, PhD, Virginia Commonwealth University Department of Forensic Science, Richmond, VA; J. Paul Brooks, PhD, VCU, Richmond, VA; Kimberly L. Lettner, MFS, Abbott Technologies, Louisa, VA*

Learning Objectives: Attendees of this presentation will gain insight into a novel forensic DNA phenotyping approach for predicting body weight and muscularity classes using microRNA expression profiles in DNA extracts from dried whole blood and saliva samples. Attendees will also learn about newly identified microRNA markers associated with distinct body composition categories, along with candidate reference genes.

Impact Statement: This presentation will positively impact the forensic DNA community by introducing useful microRNA markers for predicting body weight and muscularity of unknown individuals. These markers can be readily integrated into the existing forensic DNA phenotyping panels and workflows. This research aims to acquire environmentally impacted phenotypical information from DNA evidence without increasing sample consumption, processing time, or resource demands.

Abstract Text: Forensic DNA Phenotyping (FDP) utilizes genetic markers to predict Externally Visible Characteristics (EVCs) such as eye, hair, and skin color, serving as an invaluable tool in cases lacking known suspects or database matches.[1,2] However, predicting body composition traits like body weight and muscularity remains a significant challenge due to the complex interplay between genetics and environment.

To advance current FDP capabilities, this study investigates microRNAs (miRNAs) as alternative biomarkers. miRNAs are small, stable, non-coding RNAs that mediate post-transcriptional gene regulation.[3,4] miRNA expression is influenced by metabolic state and physical activity, making them promising markers for predicting environmentally impacted traits such as body weight and muscularity.[5,6]

This study introduces an innovative FDP approach exploiting miRNA expression profiles from DNA extracts of whole blood and saliva to predict body weight and muscularity classes. Comprehensive body composition was assessed via bioelectrical impedance analysis. Potential miRNA markers linked to body composition were identified through literature review and High-Throughput Sequencing (HTS) of selected RNA samples. These markers were then validated using Reverse Transcription-quantitative PCR (RT-qPCR) in a diverse population of 100 individuals varying in age, biological sex, ethnicity, and body composition. HTS identified several miRNAs with sufficient abundance and statistically significant differential expression across body composition groups, including miR-1246 and miR-486-3p. Literature review further supports the biological relevance of these miRNAs, as they are involved in metabolic regulation, exercise adaptation, and muscle cell differentiation. RT-qPCR analysis of 100 blood and 100 saliva DNA extracts confirmed associations between specific miRNAs and body composition traits. Linear regression models, using various body composition measures as outcomes and normalized blood miRNA expression values as predictors, revealed that miR-145-5p, let-7i-5p, and miR-106a-5p exhibited statistically significant correlations ($p < 0.05$) with assessed body composition such as Body Mass Index (BMI), fat percentage, and muscle mass percentage. In addition, machine learning models, including Support Vector Machine and Random Forest models, were trained and optimized using the population dataset, achieving moderate accuracy in predicting body composition classes.

In conclusion, this study highlights the predictive ability of miRNAs and contributes to the development of prediction models for environmentally influenced EVCs. Notably, the ability to detect miRNAs from DNA extracts reduces sample consumption and processing time while providing investigators with more identity-related information. Future work will focus on increasing sample size and further verifying identified miRNA markers to improve model performance and predictive accuracy.

B177 Next-Gen Solutions: Advancing the Detection of Degraded DNA in Forensics

Emily Quartemont, BS, Bode Technology, Laurel Hill, VA; Kristen Naughton, BS, Bode Technology, Lorton, VA; Heather Sarik, MS, Bode Technology, Lorton, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how some of the latest technology can be used to improve Short Tandem Repeat (STR) typing results from degraded forensic samples. Both the Spectrum Capillary Electrophoresis (CE) system and MiSeq FGx system allow for all Combined DNA Index System (CODIS) STR loci to be amplified at smaller fragment sizes, increasing profile success for degraded DNA amplification.

Impact Statement: This presentation aims to impact the forensic science community by providing insight into the benefits and limitations of using new technology for enhanced profiling of degraded DNA samples. The audience will learn how the Spectrum Capillary Electrophoresis (CE) system with 8-dye chemistry and Massively Parallel Sequencing (MPS) technology on the MiSeq FGx system compare to traditional 6-dye CE methods for an improved degraded DNA detection pipeline.

Abstract Text: Often in forensic casework, the DNA evidence collected can be degraded due to the environmental conditions it was collected from or the sample age. In recent years, DNA extraction techniques have been optimized to collect smaller DNA fragments from forensic sample types such as fired cartridge casings, bone, and rootless hair shafts.[1-3] These sample types often contain very low quantities of DNA and are of poor quality, which can affect how well they are amplified with the current STR megaplexes. These challenges can lead scientists to turn to other methods for degraded DNA like mini-STR analysis or non-STR technology (e.g. Insertion/Deletion markers). However, these methods are at a disadvantage by consuming more DNA extract to amplify in multiple chemistries, often generating profiles of lower discriminatory power and lacking a sufficient database for comparisons with non-STR data.[4-6] Two emerging technologies for STR analysis, MPS and the expanded 8-dye CE system, provide opportunities to address the challenges of typing degraded DNA by decreasing the average amplicon size of an entire assay while increasing the number of STR targets, subsequently increasing the overall discriminatory power and resolution of the profiles generated.[7,8]

In this study, Promega's PowerPlex 35GY (35GY) amplification kit and Qiagen's ForenSeq MainstAY (MainstAY) Prep kit were evaluated and compared with Promega's PowerPlex Fusion 6C (Fusion 6C) amplification kit to determine if more genetic information could be obtained from degraded sample material. The 35GY kit targets 35 loci in a single assay, containing the same autosomal loci targeted in Fusion 6C but with redesigned primers to decrease the amplicon lengths of the largest autosomal loci. The MainstAY kit instead relies on unique dual index adapters to multiplex 52 loci in a single assay, where the target amplicon lengths can overlap more readily without the dye channel constraint of traditional CE.

Bones, handled fired cartridge casings, and rootless hair shafts were collected and analyzed as mock evidence to mimic degraded casework samples. In addition, two artificially degraded sample sets were tested, one using Ultraviolet (UV) radiation and another using the Covaris M220 Focused-ultrasonicator, to further evaluate the kits' detection capabilities with degraded sample material. A sensitivity study testing a range of input quantities as well as an inhibition study testing the effects of common inhibitors were also included. All extracts were prepared with MainstAY, 35GY, and Fusion 6C and analyzed on the MiSeq FGx, Spectrum CE, and 3500 xL Genetic Analyzer, respectively.

For all samples that generated profiles, MainstAY and 35GY showed notable improvement compared to the traditional 6-dye chemistry, supporting the theory that the redesigned primers for smaller amplicon fragment lengths can improve STR profile results from degraded DNA. The match statistics for both 35GY and MainstAY also increased favorably for partial profiles, though with a greater increase for MainstAY profiles when considering the sequence level resolution. Overall, both technologies provide a promising solution with different advantages to overcome the common challenges of typing degraded forensic samples.

B178 Impurity Profiling: A Critical Nexus of Pharmaceutical Quality and Forensic Drug Investigation

Tahir Jamshaid, MPhil, Punjab Agriculture Food and Drug Authority, Lahore, Punjab, Pakistan*

Learning Objectives: The audience will be able to understand the significance of impurity profiling in ensuring pharmaceutical quality and its role in forensic drug investigations and will furthermore valuate regulatory and forensic implications of impurity profiling in drug safety and criminal investigations.

Impact Statement: Impurity profiling serves as a vital analytical tool that bridges pharmaceutical quality control and forensic drug investigations, ensuring both patient safety and legal accountability. In the pharmaceutical industry, identifying and quantifying impurities is essential for regulatory compliance, drug efficacy, and minimizing adverse health effects. Simultaneously, in forensic science, impurity profiling aids in tracking illicit drug manufacturing routes, detecting adulterants, and supporting law enforcement in criminal investigations.

Abstract Text: Impurity profiling has emerged as a critical aspect in both pharmaceutical science and forensic drug analysis. This study highlights the importance of impurity profiling in forensic drug testing laboratory. Impurity profiling involves the identification, characterization, and quantification of impurities encountered in drug substances and pharmaceutical products.[1] These impurities can arise from various sources, including starting materials, synthesis by-products, degradation products, and contaminants introduced during manufacturing or storage.

Regulatory agencies like the Food and Drug Administration (FDA) mandate stringent quality control measures to ensure the safety and efficacy of drug products. By the identification and quantification of impurities, forensic and pharmaceutical scientists can assess the potential toxicity and pharmacological effects of such analytes. Impurity profiling serves a unique but equally important purpose for forensic drug analysts for identifying the source, manufacturing route, and distribution network of illicit drugs.[2] By comparing the impurity profiles of drug samples seized from different locations, investigators can establish connections between drug trafficking organizations and track the movement of drugs across borders. Impurity profiling can also provide valuable evidence in legal proceedings, helping to prove the authenticity and origin of drug samples.

The methodology employed for impurity profiling typically involves a combination of analytical techniques, including chromatography, mass spectrometry, and spectroscopy. Chromatographic techniques such as gas chromatography/mass spectrometry and liquid chromatography/mass spectrometry are used to separate and identify individual impurities in a drug sample.[3] Spectroscopic techniques such as nuclear magnetic resonance spectroscopy and infrared spectroscopy are used to determine the structure and chemical properties of these impurities. The results of impurity profiling can have significant implications for both public health and law enforcement. Impurity profiling can help to prevent the distribution of unsafe or ineffective drug products, disrupt drug trafficking networks, and bring drug offenders to justice.[4,5]

In conclusion, impurity profiling is an indispensable tool for both pharmaceutical scientists and forensic drug analysts. By providing a detailed understanding of the chemical composition of drug substances and products, impurity profiling helps to ensure the safety and efficacy of pharmaceuticals and combat the illicit drug trade. The continued development and application of impurity profiling techniques will play a crucial role in safeguarding public health and promoting justice.

B179 Quantifying the Similarity of Chemical Spectra

Hana Lee, PhD, Iowa State University, Ames, IA; Alicia L. Carriquiry, PhD, Iowa State University, Ames, IA*

Learning Objectives: Participants will learn how to use statistical and machine learning methods to quantify the similarity between two chemical spectra. Spectra can be characterized by, for example, the location, height, and volume of peaks. Given two spectra, it may be of interest to determine whether they correspond to chemically indistinguishable compounds. We propose a data-based method to answer that question using a likelihood ratio.

Impact Statement: This presentation has the potential to impact the community of forensic professionals who carry out chemical analyses by exposing them to objective, reproducible methods to compare spectra. It will also impact forensic scientists in the intelligence community because the methods we propose will enable investigators to link different crime scenes or drug seizures.

Abstract Text: Forensic scientists have used spectroscopic techniques for decades to examine many different types of evidence, including drugs, DNA, explosive materials, paint, fibers and many others. Depending on the type of sample and the desired information, scientists may employ Infrared Spectroscopy (IR), Mass Spectrometry (MS), or Raman spectroscopy, to mention a few. IR and Raman spectroscopy are particularly well suited for cases where the main goal is to identify the molecular structure of a compound. These non-destructive techniques are highly sensitive and have been widely applied for the analysis of paints and fibers and the identification of particular molecules in the sample. MS, for example paired with gas chromatography, permits quantifying the composition of a compound by measuring the mass-to-charge ratio of ions produced when the substances in the sample are fragmented and separated. Many crime labs in the United States are equipped to perform one or more of these chemical analysis and, as a consequence, an abundance of this type of chemical data is routinely collected. Yet, objective, robust, and reproducible methods to extract meaningful information from these data have not been developed.[1] Forensic chemists use statistical (or chemometric) methods such as Principal Component Analysis (PCA) or Discriminant Analysis (DA), or Partial Least Squares regression (PLS) or PLS-DA to interpret spectra, and sometimes just resort to visual comparison of spectra to identify the substance. While chemometric approaches can be useful, they all have limitations and results may be difficult to interpret.

We propose an interpretable machine learning approach to calculate the value of a set of features extracted from a single spectrum or from a pair of spectra to be compared. Consider two spectra to be compared. The first step in our approach is to identify features (or attributes) that may be associated with the *similarity* between the two spectra. For example, the number of coinciding peaks may be one such feature. Intuitively, we would expect many matching peaks when the two spectra arise from samples with the same chemical make-up. Another feature of interest may be the sum of the areas separating the two spectra. For matching spectra, we would expect a small separation and therefore, a small value for the sum of areas. Useful features are those that attain different values for matching and non-matching pairs of spectra. If we can identify and measure several such features, then we can combine them into a similarity value using an algorithmic approach such as a random forest.

We illustrate this approach using publicly available databases of spectra. One such database was recently published and includes about 3,500 Raman spectra obtained from 32 different substances.[2] Results so far have been encouraging in that the approaches we propose appear to be highly sensitive and highly specific.

B180 Validation in Forensic Science: Guiding Principles for the Collection and Use of Validation Data

Henry Swofford, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will learn about five guiding principles identified by an interdisciplinary group of researchers at the National Institute of Standards and Technology (NIST) to support the forensic science community in strengthening the robustness, transparency, and reliability of validation practices.

Impact Statement: This presentation will impact the forensic science community by expanding on the definition of validation provided by the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 17025, discussing the components of validation in the context of forensic science, and identifying five key principles to guide validation activities in practice.

Abstract Text: Validation is the process of assessing whether a method or technique meets specified requirements for an intended use and is an important prerequisite for any method or technique used in scientific or technical practice, including forensic science. Results of forensic analyses are often relied upon by law enforcement officers, attorneys, and courts to make important decisions affecting life and liberty. Providing information about the validation of a forensic science method or technique is fundamental to trusting scientific analyses and criminal justice outcomes.

International standards, including ISO/IEC 17025 *General requirements for the competence of testing and calibration laboratories* and ISO 21043 *Forensic sciences* series have emphasized the importance of methods supported by validation studies. ISO/IEC 17025 is written to be industry- and sector-agnostic and generally applicable across different types of testing and calibration laboratories. While not specific to forensic science, it is the prevailing standard to which many forensic science laboratories conform and are accredited under. ISO 21043 builds upon ISO/IEC 17025 by extending those specifications in a context that is specific for forensic science. While ISO/IEC 17025 and ISO 21043 provide a general framework for laboratories to demonstrate their ability to generate valid results, they do not guarantee that laboratories are generating valid results or provide detailed guidance on how to conduct validation studies.

Practitioners recognize the importance of validation, but many often struggle to apply it in practice. Designing and conducting robust validation studies can be complex and costly. Forensic science faces additional hurdles as evidentiary materials submitted for analysis may be subject to contamination, degradation, and damage due to uncontrolled environmental conditions and other factors relating to evidence detection, collection, and handling. Accounting for a wide variety of evidentiary circumstances, such as the type, quality, or condition of materials, can be overwhelming and is often impractical in a single study. Furthermore, resources are often limited, and many laboratories are left to conduct validation studies in isolation.

This presentation is intended to help the forensic science community better understand how validation can be effectively approached. It expands on the definition of validation provided by ISO/IEC 17025, discusses the components of validation in the context of forensic science, and identifies five key principles to guide validation activities in practice, emphasizing the ongoing nature of validation, including the collection and documentation of validation data, performance characterizations, and communication of results to improve confidence in forensic methods. It also encourages collaborative and community-based approaches to validation testing, including sharing plans, materials, methods, and data to: (1) reduce resource burdens on individual laboratories performing validation testing, (2) allow laboratories to make validation decisions more quickly, and (3) enable laboratories to convey information about the accuracy and reliability of their methods with greater confidence.

B182 A Bug's Life: A Soft Ionization Mass Spectrometric Approach for the Species Identification of Unknown Entomological Evidence for Postmortem Interval Determination

Alexa Figueroa, BS, ABFE-T, Louisiana State University, Baton Rouge, LA; Robert B. Cody, PhD, JEOL USA, Inc., Peabody, MA; Rabi A. Musah, PhD, Louisiana State University, Baton Rouge, LA; Jennifer Rosati, PhD, John Jay College of Criminal Justice, New York City, NY*

Learning Objectives: Attendees can expect to learn about the use of soft ionization techniques such as Direct Analysis in Real Time High-Resolution Mass Spectrometry (DART-HRMS) and Field Desorption Mass Spectrometry (FD-MS) and their applications in forensic entomology. They will also learn how statistical analysis can be applied to the metabolome profiles revealed by the aforementioned methods to enable insect species identification that can be useful for Postmortem Interval (PMI) determination as well as geographic provenance determination of unknown entomological evidence.

Impact Statement: Facile generation of metabolome profiles combined with the application of statistical analysis of these profiles reveals unique chemical fingerprints that enable species differentiation and accurate identification of necrophagous blow fly eggs, larvae, pupae, and adults. Furthermore, the mass spectral data acquired from the empty puparial cases from which the adults emerged also contains unique species-specific chemical profiles with compounds that may be less susceptible to weathering and degradation when exposed to the elements. Thus, these molecules could potentially be used to age puparial casing evidence.

Abstract Text: Rapid approaches for accurate species identification of necrophagous insect evidence retrieved from decomposing remains is needed because of its importance for the determination of the PMI. Medicolegal forensic entomology utilizes the patterns associated with insect colonization of remains to estimate PMI. Blow flies (Family: Calliphoridae) are capable of detecting remains within minutes of death, often serving as the initial colonizers. A "back-calculation" method exists in which the time since death has occurred (i.e., PMI) can be estimated by correlating the insect species identity, environmental conditions, the stage of decomposition of the remains, and the species-specific insect life cycle timelines. The calculation determines the time since colonization by the insects, based on the assumption that the eggs were laid within a time period shortly after the death occurred. Precise species identification is essential for accurate PMI estimation, as developmental rates vary significantly among blow fly species as a function of environmental conditions.

When the retrieved entomological evidence is in the form of the juvenile life stages (eggs, larvae, pupae) or the puparial casings from which the adult blow flies emerged, species assignment can be very difficult because the specimens are similar in appearance across many species.

Reported here is a novel and rapid approach utilizing the soft ionization techniques of FD-MS and DART-HRMS coupled with statistical processing for insect species determination. Mass spectral analysis was used to generate the chemical profiles for 16 blow fly species from 14 geographical regions. Support Vector Machine (SVM) statistical models were created for each life stage, all resulting in leave-out cross validations of 95% or higher with external validations of 90% or higher accuracy for each.

The statistical analysis by DART-HRMS revealed that there are *m/z* values unique to each species (e.g., *m/z* 586.41388 in *C. livida* pupae and *m/z* 635.51434 in *P. regina* larvae). It also enabled differentiation between specimens of the same species and life stage based upon geographic provenance (e.g., *m/z* 293.24806, $C_{19}H_{32}O_2$, was only detected in *L. cuprina* Arizona egg samples but not in the Texas samples).

The FD-MS analysis of empty puparia revealed that the chemical basis for the successful differentiation of species was the detection of masses associated with alkanes as large as $C_{55}H_{102}$, and sterols and esters as large as $C_{58}H_{118}O_2$, many of which have yet to be reported in the literature in association with insects. Other compounds were detected that were unique to particular species, such as 3-methyltricosane (*C. vicina*), 11,11-dimethylhenicosane (*C. latifrons*), and 11-decyltetracosane (*L. sericata*). There were 31 *m/z* values which were important for discrimination that were detected by FD-MS, but which could not be detected by Gas Chromatography (GC) due to their non-volatility. The presence of these compounds could facilitate the development of models for species prediction based on chemical profiles that feature higher molecular weight molecules, which are more stable to weathering under field conditions and can facilitate retention of the accuracy of the species prediction models.[1]

B183 The Detection of Oral Fluid Stains on Fabric Via Solution Extraction Combined With Deep Ultraviolet Raman Spectroscopy

Igor K. Lednev, PhD, University at Albany, SUNY, Albany, NY; Mohamed O. Amin, PhD, University at Albany, SUNY, Albany, NY; Entesar Al-Hetlani, PhD, Kuwait University, Safat, Al Asimah, Kuwait*

Learning Objectives: After attending this presentation, attendees will be aware of the: (1) limitations of current methods for biological stain analysis during forensic investigation; (2) significance of a novel non-destructive method for confirmatory identification of saliva traces; and (3) advantages of deep Ultraviolet (UV) Raman spectroscopy combined with machine learning in forensic investigation

Impact Statement: This presentation will impact the forensic science community by demonstrating a newly developed capability of deep-UV Raman spectroscopy for detecting and confirmatory identification of saliva traces on fabric prior to DNA analysis.

Abstract Text: DNA phenotyping plays a central role in modern practical forensics, yet an overwhelming amount of evidence creates significant backlogs in all major crime laboratories. A fast, non-destructive test of a potential biological stain prior to DNA phenotyping should reduce the number of irrelevant samples for the analysis and increase the efficiency of the overall process. Evidence items recovered from the crime scene can often include body fluid traces such as saliva.

This proof-of-concept study demonstrates the effectiveness of deep-UV Raman spectroscopy in identifying saliva stains on substrates such as cotton, polyester, and blue denim, commonly encountered in forensic investigations. Through spectral interpretation and statistical analysis, this study compares Raman spectra from saliva extracted from substrates with pure saliva spectra. Additionally, comparative analysis with Near-Infrared (NIR) Raman spectroscopy to deep-UV Raman spectroscopy was performed. Distinct advantages of deep-UV Raman spectroscopy were determined, including reduced sample preparation requirements and the absence of fluorescence background, enhancement of the signal-to-noise ratio, and simplified data preprocessing. Using statistical analysis methods like principal component analysis and partial least-squares discriminate analysis, differentiation between saliva and non-saliva samples was possible. Overall, this study underscores the versatility and potential of deep-UV Raman spectroscopy as a valuable tool in forensic science.

This project was supported by Award No. 2017-DN-BX-0135 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. B184 The Fungicide Did It: False Negatives and Decreased Sensitivity of Heme Tests on a Leather Substrate

Lily Manzi, BA, Loyola University New Orleans, New Orleans, LA; Allyn Schoeffler, PhD, Loyola University New Orleans, New Orleans, LA; Anna S. Duggar, PhD, Loyola University New Orleans, New Orleans, LA*

Learning Objectives: Attendees will be made aware of the potential for presumptive and confirmatory false negative test results as produced by bloodstains on leather casework samples and the chemicals that may cause the error. Participants will further learn how a common preventative fungicide can be shown to chemically affect hemoglobin's structure, potentially causing the observed false negatives.

Impact Statement: The presentation alerts practitioners to a widely unrecognized shortcoming of three different classes of blood tests, which can impact forensic decision-making at the scene and in interdisciplinary laboratory workflow. Further, the study illuminates the biochemical reason behind the failure, perhaps providing a foundation for remediative efforts in future.

Abstract Text: This study expands upon fundamental work performed in the past decade to codify anecdotal reports that leather substrates interfere with common presumptive tests for blood.[1,2] Among the most widely employed presumptive tests for blood are those based on the peroxidase-like catalytic properties of heme, the iron-containing prosthetic group in hemoglobin. In addition to the heme-catalyzed color tests for blood, two other approaches target heme and hemoglobin: microcrystalline testing, in which microchemical reactions form derivative crystals with distinct optical properties; and immunochromatographic assays, which detect primate hemoglobin via antibody-antigen binding. Historically, all three classes of forensic blood tests are known to experience attenuated positive results in the presence of a leather substrate. These false negatives can have implications not only for crime scene interpretation but also for laboratory workflow, as blood tests often inform decisions about further DNA analysis.

This study evaluates multiple possible chemical contributors potentially responsible for these false negatives, each possibly found residually in leather as a byproduct of the tanning process. Among the candidates tested, 2-(Thiocyanomethylthio)Benzothiazole (TCMTB), a commonly used antifungal agent, was identified as a key chemical of concern. Circular dichroism spectroscopy, a well-established biophysical technique for quantifying structural changes in proteins, was then employed to investigate the interaction between TCMTB and hemoglobin.[3] Results indicate that the TCMTB fungicide directly alters the structure of the hemoglobin molecule, likely giving rise to the observed interference across all three test modalities.

These findings advance understanding of leather-substrate-based interference in forensic serology and serve as a reminder to practitioners of the need to account for material-specific interactions in presumptive testing. Potential strategies for remediation of the effect will also be considered.

B185 Moving Toward a More Sustainability Forensic Science

Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA*

Learning Objectives: After attending this presentation, attendees will gain a better understanding of the present-day status of Green Analytical Chemistry (GAC) methods in the field of forensic science as well as the green analytical tools that are available and have been used in forensic applications.

Impact Statement: This presentation will impact the forensic community by raising awareness of greenness assessment tools for forensic chemistry and toxicological methods and bringing attention to the need for more sustainable and greener methodologies in the forensic field.

Abstract Text: The purpose of this presentation is to raise awareness of green assessment tools for forensic chemistry methods that are available and to promote processes towards a more sustainable practice of forensic science.

The development of environmentally sustainable analytical methods for chemical analysis should be the goal of every laboratory. The development of such methods requires the chemistry to be as environmentally friendly or "green" as possible. The concept of "Green Chemistry" was proposed in the 1990s by Anastas and Warner who proposed "Twelve Principles of Green Chemistry," which focused on synthetic chemistry.[1] Green Chemistry is the use of a set of principles that reduces or eliminates the use or generation of hazardous substances. GAC has subsequently developed as an emerging field that emphasizes the development of environmentally sustainable analytical methods for chemical analysis. GAC is gaining momentum in various chemical industries but has not yet become a popular focus in forensic chemistry or other areas of forensic science.[2]

The first principle of GAC highlights sample preparation as a major contributor to environmental, health, and safety concerns in analytical methods. In 2022, the concept of Green Sample Preparation (GSP) was presented.[3] This concept encourages the elimination of sample preparation and advocates for direct analysis of samples; however, this is not always a viable alternative in forensic analysis. In forensic chemistry and toxicological analysis, solventless extraction or reduced solvent usage and the use of renewable sources are desirable. The use of sustainable and green solvents in sample preparation have been reported for various substances in the industrial laboratory and in the near future will be standard operating procedure for conducting sample preparation.

A review of the recent literature indicates research trends toward greener methods in forensic science, in particular sustainable methods in forensic toxicology are being reported. This is a good trend, but these greener methods need to be implemented into practice. Presently, the development of sustainable methods and greenness assessment of existing methodology is not a major priority in forensic science laboratories.

The purpose of this presentation is to highlight some green analytical tools, including greenness assessment metrics, that have been used in forensic chemistry applications and to bring attention to the need for more sustainable and greener methodologies in the forensic field. Examples of sustainable analytical methods reported in forensic chemistry and toxicology will be presented. The metrics for the evaluation of the greenness for the analytical methodology used to analyze Novel Psychoactive Substances (NPS) will be presented.

B186 The Three Stages of Standards Acceptance: A Groundhog Day's Guide to Implementation

Vincent J. Desiderio, MS, National Institute of Standards and Technology, Gaithersburg, MD; Allison Getz, MS*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees will gain insight into the three stages of standards acceptance: anger, ambivalence, and approval. Drawing parallels from the movie *Groundhog Day*, attendees will learn the efforts the Organization of Scientific Area Committees (OSAC) is taking to avoid the "standards" time loop and realize the transformative potential that implementing standards can have.

Impact Statement: The movie *Groundhog Day* offers a compelling metaphor for the challenges and transformative potential inherent in standards implementation. Like the movie's main character, Phil Connors, reliving the same day repeatedly, forensic service providers often face repetitive cycles of trial, error, and refinement in adopting new standards. Phil's journey—from frustration and resistance to self-awareness, growth, and ultimately service to others—mirrors the process of moving beyond initial compliance to truly embracing standards to improve outcomes for all stakeholders.

Abstract Text: Along with AAFS 2026, February also brings Groundhog Day! In the movie *Groundhog Day*, Phil Connors, a cynical TV weatherman, becomes trapped in a time loop, repeatedly reliving the same day. As he initially exploits the situation for selfish gains, Phil eventually undergoes a profound transformation, recognizing the importance of patience, persistence, and progressive growth needed to finally break free from the endless cycle.

When it comes to standards, some forensic service providers might feel like they're living in a similar time loop—having and hearing the same conversations about the same issues . . . over and over again. During this session, we'll highlight some of these déjà vu conversations, use *Groundhog Day* to illustrate some key parallels with the stages of standards acceptance (anger, ambivalence, approval), and describe the efforts the OSAC for Forensic Science is taking to break the "standards" time loop, including sharing the latest implementation data.

Developing and implementing standards is not a one-time event but a continuous journey that requires reflection, adaptation, and persistent effort, much like the repetitive but progressively improving cycle portrayed in *Groundhog Day*. Both the movie and the process of standards implementation share a key insight—lasting change and meaningful progress emerge not from repetition alone, but from evolving one's mindset and actions to better serve the greater good.

B187 Developing an End-to-End Workflow to Perform Crime Scene Investigation and Training in Virtual Reality

Vincenzo Rinaldi, MSc, Leverhulme Research Centre for Forensic Science, Dundee, Scotland, United Kingdom; Niamh Nic Daeid, PhD*, University of Dundee, Dundee, Scotland, United Kingdom*

Learning Objectives: After attending this presentation, attendees will: (1) gain technical knowledge of current state-of-the-art techniques in crime scene documentation aimed at supporting digital documentation; (2) learn about a systematic data capture procedure optimized for acquisition in real-world scenarios; and (3) assess the visual fidelity of immersive reconstructions and evaluate their applicability in both educational and operational contexts.

Impact Statement: Participants will have informed and realistic expectations on the applicability of immersive technology to crime scene analysis. The systematic data acquisition technique, supported by open-access peer-reviewed documents, will enable participants to start collecting data suitable for 3D reconstruction.

Abstract Text: This presentation will explore the use of Virtual Reality (VR) within the field of forensic science. Recent advancements in immersive technologies hold the potential to improve the education and training of professionals in this field, create more affordable and customized assessment processes, and enhance the documentation of crime scenes, thereby enabling remote collaboration and minimizing scene contamination.

As part of the presentation, we will showcase the development of a virtual training village specifically designed to simulate complex crime scenes. Participants will be provided with a thorough understanding of the essential components required for carrying out the acquisition of necessary data at the crime scene, optimized to enable accurate 3D scene reconstruction.

Additionally, we will cover the technical aspects involved in the digital documentation of crime scenes. This includes photographic recording methods, various photogrammetry techniques, and the optimization of user experience when employing immersive technologies.

Attendees will also have the opportunity to engage in hands-on activities, allowing them to navigate and analyze challenging crime scenes in VR. This experience will enable participants to understand both the advantages and limitations of applying immersive technologies in the training and testing of forensic professionals, as well as their practical applications in real-world operational settings.

B188 That's Dope: A Novel Approach for the Differentiation of Δ9-THC Isomers in Cannabis

Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; Emma Hardwick, BA, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX; Christopher M. Zall, PhD, Sam Houston State University, Huntsville, TX; Christany Liggins, BS, Sam Houston State University, Huntsville, MS*

Learning Objectives: After attending this presentation, attendees will have learned about a novel approach for the differentiation of Δ9-Tetrahydrocannabinol (Δ9-THC) isomers using Cu-phosphine ion complexation. The audience will learn how differences in the selective binding affinity of various Cu-phosphine ligands affect complex formation with cannabinoids such as Δ9-THC, Cannabidiol (CBD), and Δ8-Tetrahydrocannabinol (Δ8-THC). Attendees will understand how the structural differences influence complex formation and fragmentation behavior, enabling the differentiation of isomeric cannabinoids. This work provides the foundation for the development of an alternative approach for hemp and marijuana differentiation using Cu-phosphine ion complexation.

Impact Statement: This presentation will impact the forensic science community by providing the first comprehensive characterization of Cu-phosphine cannabinoid complexes for the differentiation of cannabinoid isomers. The selective binding of Cu-phosphine complexes to Δ9-THC, CBD, and Δ8-THC leads to the formation of characteristic Cu-phosphine cannabinoid complexes, enabling differentiation of these structural isomers. These findings lay the groundwork for future seized drug applications in distinguishing hemp and marijuana based on selective complex formation.

Abstract Text: The 2018 Agriculture Improvement Act established a 0.3% Δ^9-THC threshold to differentiate legal hemp from illegal marijuana. *Cannabis sativa* L. containing greater than 0.3% Δ^9-THC on a dry weight basis is classified as marijuana, which remains a Schedule I controlled substance. Given the prevalence of suspected marijuana samples in forensic casework, there is a need for a reliable method to differentiate hemp and marijuana. Gas Chromatography/Mass Spectrometry (GC/MS) is the traditional technique for hemp and marijuana differentiation; however, the high temperature of the GC inlet leads to decarboxylation of acidic precursors and potential cannabinoid conversion. Under Liquid Chromatography/Electrospray Ionization/Tandem Mass Spectrometry (LC/ESI/MS/MS) conditions, the main cannabinoids present in hemp and marijuana, CBD and Δ^9-THC, are nearly indistinguishable based on product ion mass spectra alone due to their isomeric nature. As a result, chromatography is heavily relied upon for cannabinoid identification, which can be difficult due to the co-elution of isomers. The central hypothesis of this research is that Δ^9-THC isomers can be differentiated using Cu-phosphine ion complexation and ESI/MS/MS.

Direct injection ESI with an Agilent 6530 quadrupole Time-Of-Flight (qTOF) mass spectrometer was used for analysis. Eleven Cu-phosphine complexes were synthesized and evaluated for their ability to differentiate cannabinoid isomers, using ligands with varying properties such as denticity (i.e., monodentate vs. bidentate), chelating bite angle, electronic properties, and steric bulk. The following cannabinoids were analyzed with and without the presence of Cu-phosphine complexes: Δ^9-THC, CBD, ^{8}-THC, exo-tetrahydrocannabinol (exo-THC), Δ^{10}-tetrahydrocannabinol (Δ^{10}-THC), $\Delta^{6a,10a}$-tetrahydrocannabinol ($\Delta^{6a,10a}$-THC), cannabicitran (CBT), cannabichromene (CBC), cannabigerol (CBG), cannabinol (CBN), tetrahydrocannabinolic acid (THCA), cannabidiolic acid (CBDA), Δ^9-tetrahydrocannabinol-d_9 (Δ^9-THC-d_9), and Δ^9-tetrahydrocannabinol-d_3 (Δ^9-THC-d_3). In addition to full scan mass spectra, product ion spectra were collected with activation energies of 15-45 eV. Cu-phosphine cannabinoid complexes were characterized to identify characteristic precursor ions or product ions for cannabinoid differentiation.

The formation of Cu-cannabinoid complexes enabled the differentiation of major cannabinoids, such as Δ^9-THC, CBD, and Δ^8-THC. For example, fortifying cannabinoid solutions with $[Cu((R)BINAP)(ACN)_2]BF_4$ results in the formation of characteristic ions at *m/z* 1013 $[\Delta^9\text{-THC+Cu+BINAP+O-2H}]^+$ and *m/z* 1135 $[\Delta^9\text{-THC+2Cu+BINAP+2O+ACN}]^+$ for Δ^9-THC, whereas only one characteristic ion forms for Δ^8-THC at *m/z* 1013 $[\Delta^8\text{-THC+Cu+BINAP+O-2H}]^+$. The oxygenated Cu-phosphine cannabinoid complexes form selectively for Δ^9-THC and Δ^8-THC, whereas no charged complex forms for CBD. The MS/MS product ion spectra were used for structural elucidation of the Cu-cannabinoid complexes. Whereas $[Cu((R)BINAP)(ACN)_2]BF_4$ enabled cannabinoid isomer differentiation, this was not the case for all Cu-phosphines analyzed in this study. These results demonstrate that the choice of the phosphine ligand significantly affects the selectivity of cannabinoid binding and thus, the ability to differentiate cannabinoid isomers. Extracts of authentic cannabis samples were analyzed to evaluate the efficacy of this method under real-world conditions. The results of this study provide critical insight into the potential of Cu-phosphine ion complexation as a viable approach for differentiating cannabinoid isomers present in hemp and marijuana. Incorporation of Cu-phosphine ion complexation into chromatographic methods has the potential to provide an additional layer of confidence for cannabinoid isomer identification.

B189 Forensic Alcohol Testing of Jello Shots Given to Children

Laura M. Labay, PhD, NMS Labs, Horsham, PA; Lee M. Blum, PhD, NMS Labs, Horsham, PA; Michael E. Lamb, MS, NMS Labs, Horsham, PA; Justine Drake, MSFS, NMS Labs, Horsham, PA; Nina McCullough, BA, NMS Labs, Horsham, PA*

Learning Objectives: This presentation will: (1) describe the unique analytical challenges associated with quantifying ethanol in gelatin-based matrices, (2) explain the workflow used to detect and quantify ethanol in gelatin-based matrices from receipt and sample preparation through analysis and interpretation, and (3) recognize the public health implication of alcohol-laced consumables being provided to minors at school.

Impact Statement: This presentation will impact the forensic science community by providing a means to quantify the ethanol content in a complex food matrix, encouraging laboratories to create adaptable workflows that can accommodate alternate matrices, and raising awareness about the covert administration of alcohol to children at school functions.

Abstract Text: A Jello shot is a colloquial term for a mixture of gelatin and alcohol, typically prepared in small portions and consumed as a shot or shooter. They are brightly colored, and their sweetness serves to mask the taste of alcohol, increasing the risk of unintentional consumption by minors. Analytical testing to determine ethanol content presents several challenges because of their gelatinous consistency, possible non-homogenous distribution of ethanol throughout, and the need to minimize evaporative loss during sample preparation.

We present a case of an incident at an elementary school in which gelatin-based treats containing alcohol were consumed by students during a classroom party. Several children experienced symptoms such as stomachaches and headaches, with one child reporting vomiting. Subsequent investigation included the submission of leftover treats for laboratory analysis to determine if ethanol was present and if so, its amount. A total of five Jello shots in souffle cups were submitted. Four were in one vacuum-sealed bag and one was separately packaged in a second vacuum-sealed bag. To preserve most of the samples, the Jello shot that was in its own bag was selected for testing.

The Jello shot was frozen in its bag at -20°C. Two 0.5 g portions were chipped away and each directly transferred into its own 20 mL headspace vial with a butyl stopper. The sealed vials were placed in an approximately 30°C water bath and allowed to liquify. Once liquified, 4.5 mL deionized water was added through the septa to create 10-fold dilutions of each sample. Serial dilutions were made using deionized water to create sets for standard addition work. From one sample, a 1:10000 dilution was prepared, while 1:100 and 1:1000 dilutions were prepared from the other sample. For each dilution, four replicate samples were aliquoted, three were fortified with ethanol at 5, 10, and 25 mg/100 g, and one was left unfortified. An internal standard (0.0125% 1,4-dioxane) was added to each vial. Analysis was performed by dual-column headspace-gas chromatography with split injection and flame ionization detectors. Quantitative values for each set were calculated by plotting the ethanol concentration versus its analyte-to-internal standard response ratio and generating a trendline between all data points. The ethanol concentration was determined by the x-intercept of the respective trendlines. The 1:10000 test was over-diluted, but valid test results were obtained for the 1:100 and 1:1000 sets with correlation coefficients ≥0.997. The reported quantitative result determined by standard addition showed ethanol at 9% w/w. This finding is consistent with the amount of ethanol present in some alcohol-containing beverages.

This case highlights the potential for alcohol to be surreptitiously administered to children. Finally, the provided workflow can be used to determine ethanol content not only in Jello shots, but also in other non-liquid matrices.

B190 Recent Trends in Fentanyl Adulteration: Results From the Near Real-Time Drug Checking RaDAR Program

Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how near real-time drug checking can be used to inform forensic scientists on current drug trends. Attendees will be provided with insights into the current observations on fentanyl adulteration as well as information on new drugs and adulterants that have been recently detected within the street drug supply.

Impact Statement: This presentation will impact the forensic seized drug and toxicology communities by providing key insights into what the current drugs and adulterants are in the street drug supply as well as quantitative trends regarding fentanyl purity. This information can better inform what the analytical methods used for forensic casework are and help laboratories ensure there spectral libraries are up-to-date.

Abstract Text: Understanding changes in the makeup of the street drug landscape is critical for law enforcement, forensic science, and public health entities. To assist in providing as near real-time information as possible, the Rapid Drug Analysis and Research (RaDAR) program was established. The program provides rapid (< 48 hour) turnaround and qualitative and quantitative testing of drug product and drug paraphernalia samples collected across the United States. Using a mass spectrometry-centric platform, the RaDAR program aims to provide near-complete chemical analysis of samples, emphasizing identification and quantitation of adulterants, cutting agents, and novel compounds.

This presentation will discuss the historical and real-time trends in fentanyl adulteration observed in samples received by the RaDAR program. Over the past year, rapid and dynamic shifts in the fentanyl supply have been observed, including the introduction of new α_2-agonists, local anesthetics, industrial chemicals, and novel psychoactive substances. Data on these compounds will be presented through both a qualitative (prevalence of a compound within the samples received) and quantitative (amount of compound typically found in a sample) perspective.

Specific adulteration trends that will be discussed include BTMPS, medetomidine, lidocaine and tetracaine, nitazenes, and other novel psychoactive substances. BTMPS, an industrial chemical initially found in the fentanyl supply in mid-2024, showed a dramatic increase in prevalence through November 2024—where roughly four in ten fentanyl samples contained the compound—before a gradual and sustained decline. The decline in prevalence was mirrored with a decrease in the amount of BTMPS in a sample, dropping from a median of approximately 15% by weight to less than 5% by weight over a one-year period. Medetomidine, however, has seen a noticeable increase in both prevalence and amount over the past year. It is now being regularly detected in Western United States regions and has surpassed xylazine in terms of prevalence in samples from the Eastern United States.

In addition to discussing current adulteration and purity trends, this presentation will provide information on the most recently detected compound identified in RaDAR samples. Ongoing efforts to better understand and map the movement of new compounds through street drug supply will also be discussed.

B191 Thirdhand Exposure to Drugs From Residual Contamination: An Analysis of Seized Contaminated Vehicles and Experimental Tests From Simulated Smoking of Methamphetamine in an Uncontaminated Vehicle

Stewart Walker, PhD, Flinders University, Adelaide, South Australia, Australia; Gemma L. Kerry, BSc, Flinders University, Adelaide, South Australia, Australia; Jackie Wright, PhD, Environmental Risk Sciences Pty Ltd, Carlingford, New South Wales, Australia; Kirstin E. Ross, PhD, Flinders University, Bedford Park, South Australia, Australia*

Learning Objectives: This presentation will impart an understanding of the potential extend of thirdhand exposure to drugs (Amphetamine-Type Stimulants [ATS]) in contaminated vehicles through analysis of both criminally contaminated and experimentally contaminated vehicles. Results from surface swabs, air sampling, and analysis of fabric patches and witness plates in a vehicle that was exposed to three methamphetamine smoking events (0.1, 0.1, and 0.4mg of $60 methamphetamine) followed by three periods of venting will indicate the potential for distribution and accumulation of drugs in different parts of the vehicle and the effectiveness of potential remediation steps.

Impact Statement: The consequences of firsthand exposure (user) and secondhand exposure (not taking drugs but living with user or synthesizer) are well documented. Contamination of houses either due to synthesis or smoking of drugs is also well studied.[1-3] This presentation deals with the potential for vehicles to become contaminated due to smoking or synthesis or used to transport drugs to sell. Analyses of previously contaminated vehicles that have been seized and a "clean" vehicle exposed to controlled smoking of methamphetamine has enabled the distribution of methamphetamine in different parts of the vehicles, in the air, and on different fabrics as witness plates to be determined. The initial areas of contamination were determined (for example, high residual levels above the smoker) and the redistribution of drugs over time show the potential for innocent people (especially children) to be exposed to ATS by sitting and breathing in vehicles previously contaminated by smoking.

Abstract Text: The two previously contaminated vehicles were based in Melbourne, in the state of Victoria, and made available by the owning company to the researchers who traveled from Sydney, New South Wales, and Adelaide, South Australia, to collect samples. Initially, air monitoring was completed by placing air pumps with activated carbon tubes and resin sorbent tubes. [4] Then swabs were collected from various parts of the cars' interiors. For the car that was so contaminated it was to be destroyed, parts of the interior, including dashboard, seats, and roof lining, were removed and brought to Flinders University, Adelaide, South Australia, for further testing.

The uncontaminated vehicle was donated by a company in Adelaide and positioned in a secure area on Flinders University campus. Three sequential smoking events, using 0.1, 0.1, and 0.4 mg of 60% methamphetamine, were carried out, followed each time by sampling by air and swabs and also squares of fabrics (cotton, polyester ,and typical car seat fabric) and tiles as witness plates were place throughout the vehicle, including the trunk/boot that was not isolated from the passenger compartment of the car. Results from a modified National Institute for Occupational Safety and Health (NIOSH) method showed an increase in methamphetamine contamination in different parts of the car. Temperature and humidity were also measured throughout the experiments. These smoking events were followed by venting, where the vehicle was left with windows opened during the summer months of January and February. Three testing events were carried out during venting that showed a decrease in methamphetamine throughout the vehicle. Results from the analysis at different times show the distribution of methamphetamine in different parts of the vehicle and how there is a potential to decontaminate vehicles by venting.

The final conclusions from this research indicate the potential distribution of methamphetamine throughout the vehicle caused by smoking in the driver's seat. Temperature variations during the experiments also indicated potential for revaporization and redistribution of methamphetamine throughout the vehicle. The consequence for innocent people, especially children, who may be sitting in a car with previous methamphetamine contamination is also presented.

B192 The Detection and Quantification of Synthetic Cannabinoids and Other Novel Psychoactive Substances in Jail Contraband

Max T. Denn, MS, Center for Forensic Science Research & Education, Horsham, PA; Nicholas Khorozov, MS, Center for Forensic Science Research & Education, Willow Grove, PA; Barry K. Logan, PhD, Center for Forensic Science Research & Education, Horsham, PA; Alex J. Krotulski, PhD, Center for Forensic Science Research & Education, Horsham, PA; Joshua S. DeBord, PhD, Center for Forensic Science Research & Education, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will be able to describe the analysis of contraband materials found in jail settings and their contents, including synthetic cannabinoids and other Novel Psychoactive Substances (NPS). The audience will compare the contents of contraband to what is available on the street and gain an understanding of the inherent risks to jail populations posed by contraband material.

Impact Statement: This presentation will benefit the forensic science community by highlighting the creative means used to smuggle synthetic cannabinoid-containing contraband into jails and the risk they represent to vulnerable populations. A better understanding of contraband materials and exposure dosages may explain the differences in observed symptoms of synthetic cannabinoid intoxications.

Abstract Text: The use of Synthetic Cannabinoid Receptor Agonists (SCRAs) in jails has recently increased in the United States and around the world. Their popularity in jails is due to the ease with which they can be impregnated into physical substrates, often letters and other paper products, and the fact that SCRAs are not tested for in routine toxicology panels. The toxicity of individual SCRAs are not well characterized, but common toxic effects include tachycardia, agitation, and seizures. The recreational use of SCRAs in jail settings represents potential harm due to a lack of awareness of their identity, concentrations, dose-to-dose variability, and the contents of the materials.

The Center for Forensic Science Research and Education (CFSRE) partners with county corrections systems to analyze contraband materials suspected of containing SCRAs and/or other drugs. All samples were confiscated within jail systems and submitted to the CFSRE for testing and surveillance purposes. For qualitative analysis, samples were diluted in methanol and prepared by both acidic and basic liquid-liquid extractions before analysis by both gas chromatography/mass spectrometry and liquid chromatography/quadrupole time-of-flight/mass spectrometry. Quantitative analysis was performed by methanol dilution and liquid chromatography/tandem quadrupole mass spectrometry.

The most frequently detected SCRA was MDMB-4en-PINACA. It was also the most identified SCRA in toxicology and chemistry casework analyzed at the CFSRE in 2024, providing evidence that contraband SCRA markets mirror more widespread illicit drug markets. Several other NPS were detected, including 2F-2-oxo-PCE (hallucinogen), metonitazene (opioid), and protonitazene (opioid). The presence of different NPS classes in the jail samples, often co-occurring, is reflective of the dynamic nature of SCRA markets and is worrisome from a health perspective as these substances can be deadly both on their own and from the combined effects of SCRAS with other classes of drugs.

Toxicity from SCRA use in jails can be compounded by a lack of uniformity of distribution within the substrate, leading to “hot spots” where the drug concentration is higher than that of the surrounding areas. When consumed, these hot spots can produce severe adverse effects, including lethal outcomes. We developed and validated methods to measure variations in concentrations of SCRAs across individual exhibits by sampling adjacent sections (e.g., 1.5 cm x 1.5 cm squares) of paper samples. Three authentic exhibits found to contain MDMB-4en-PINACA were quantified using this approach. Two exhibits were sampled in a grid format while the third contained smaller strips of paper in single dose form. SCRA concentrations varied significantly across the sheet samples with both “hot” and “cold” spots detected. MDMB-4en-PINACA amounts varied widely on one exhibit, ranging from 0.81-9 mg per subsection. Measurements of five 2 cm-long strips of paper (presumed single doses) were found to contain, on average, 522±161 µg and MDMB-4en-PINACA and 83±29 µg of MDMB-INACA. These results verify the presence of significant doses of SCRAs and other NPS in contraband papers from jails and demonstrate the variability from dose to dose within an exhibit.

B193 Resolving the "Unresolvable" Tandem Mass Spectra of the Isomers THC and CBD Using the Expert Algorithm for Substance Identification (EASI)

Alexandra I. Adeoye, MS, West Virginia University, Morgantown, WV; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: After attending this presentation, attendees will understand the benefit of using an intuitive and kinetic-based algorithm known as EASI to distinguish/identify the tandem mass spectra of Tetrahydrocannabinol (THC) from Cannabidiol (CBD) and other isobaric cannabinoids like Cannabichromene (CBC). THC and CBD have long been accepted as unresolvable by only their positive ion tandem mass spectra.

Impact Statement: This work provides an algorithm (EASI) capable of identifying substances from their tandem mass spectra, even when collected under different activation conditions and/or on instrument platforms upon which reference spectra are not available. EASI minimizes false identification rates and maximizes the identification power of tandem mass spectrometry for the identification of seized drugs.

Abstract Text: In previous work, we have demonstrated that EASI can be used to model and explain more than 90% of the variance in the branching ratios in replicate electron-ionization mass spectra of cocaine, fentanyl analogs, and cathinones.[1-3] The algorithm is founded on the kinetics of unimolecular reaction (fragmentation) rate theory, and it is most useful when humans struggle to distinguish substances from their spectrally similar analogs.[1] Here, we extend the algorithm to tandem mass spectra obtained from protonated molecular ions, such as from Electrospray Ionization (ESI) and Direct Analysis in Real Time (DART). Replicate Tandem Mass Spectrometry (MS/MS) spectra were collected for several cannabinoid isomers, including, THC and CBD, using a quadrupole Time-Of-Flight (qTOF) mass spectrometer, a triple quadrupole mass spectrometer, and an Orbitrap mass spectrometer. Despite the differences in collision gases and energies, EASI was superior to other machine-learning algorithms for discriminating between the tandem mass spectra of THC and CBD, especially, when making inter-instrument comparisons. At each energy of the training set, the tandem mass spectra for CBD and THC are visually indistinguishable, so manual classification rates are no better than a coin flip at 50%. After splitting the data into a training set and test set, conventional algorithms that use a consensus spectrum as the exemplar at each collision energy provide classification accuracies of 61-90%, depending on the collision energy. In contrast, EASI applied to the same dataset provides classification accuracies of 86-96%. EASI classification rates are also superior to binary classification using the Mahalanobis of each spectrum relative to the training set. EASI offers a paradigm shift in the ability to make reliable identifications of isomeric and isobaric analogs in the absence of reference spectra on the same instruments.

B194 An Investigation Into the Decreased Abundance of Heroin in a Complex Mixture: A Gas Chromatography/ Mass Spectrometry (GC/MS) Case Study of Seized Drug Evidence

Mikaela Romanelli, MS, Drug Enforcement Administration, New York, NY*

Learning Objectives: This presentation is a case study in the area of seized drug analysis regarding the investigation of a decreased abundance of heroin in a complex mixture with an increased injection volume using GC/MS. Attendees will follow the analysis scheme of a real-life case sample with component interactions that led to the mono-deacetylation of heroin to give O6-Monoacetyl Morphine (O6-MAM). Additionally, they will learn about laboratory methods employed to prevent or limit the heroin to O6-MAM conversion.

Impact Statement: Data produced as a result of this research indicated that heroin, in the presence of a large excess of acetaminophen, can be caused to undergo a conversion to O6-MAM to varying degrees. This leads to a decreased abundance of the casework sample's primary Schedule I controlled substance. Since the undertaking of this research, there have been approximately five additional cases at the Drug Enforcement Administration (DEA) Northeast Laboratory where this phenomenon has been observed. Investigation into the cause of this occurrence assisted in determining possible analytical limitations and considerations in the identification of heroin and heroin-related substances within complex sample types frequently encountered in the Northeast region of the United States.

Abstract Text: During the course of routine street-level distribution glassine exhibit analysis, a complex mixture was detected using the DEA standardized Global Uniform Analysis and Reporting of Drug-Related Substances (GUARDS) Gas Chromatography/Mass Spectrometry (GC/MS) method. This mixture included low-level controlled substances heroin (primary) and fentanyl/p-fluorofentanyl (secondary/tertiary) as well as significantly larger amounts of acetaminophen, Bis(2,2,6,6-Tetramethyl-4-Piperidyl) Sebacate (BTMPS), a sugar suspected to be mannitol, and other suspected compounds. Due to the relatively low level of the controlled substances present, following initial injection of the sample vials using the native split level of the GUARDS GC/MS (50:1), the sample vials were subsequently reinjected on the same instrument using the same method with the split ratio adjusted to 10:1. The resulting data from the 10:1 split run demonstrated a decrease and near-complete disappearance of the heroin peak to a baseline level. Some conversion of heroin to O6-monoacetyl morphine (O6-MAM) as a consequence of GC/MS analysis is to be expected; however, the disproportionate 885% increase in the level of O6-MAM as compared to other compounds within the sample was not anticipated based upon previous samples commonly seen in the DEA laboratory system.[1,2]

The initial data indicates the mono-deacetylation of heroin to give O6-MAM and a decreased abundance of the Schedule I primary controlled substance. Due to the complexity of the casework sample matrix, the source of this conversion was determined using standard reference material solutions that were prepared for the major components (i.e., heroin, acetaminophen, and BTMPS) at concentrations derived from sample estimation and quantitation data from analysis of the exhibit. Acetaminophen and BTMPS solutions were individually added to a heroin solution and analyzed via GC/MS using the GUARDS method with varying decreased split ratios. The resulting data indicated that, in the presence of high concentrations of acetaminophen, heroin is mono-deacetylated to O6-MAM. Additionally, observation of N,O-Diacetyl-P-Aminophenol (DAPAP), which was not present in any standard solutions prepared, supports the theory that acetaminophen (Acetyl-P-Aminophenol or APAP) acted as a receptor for a transacylation with heroin.[3] Reducing the amount of acetaminophen present within a complex heroin-containing sample solution via careful choice of solvent (e.g. chloroform, or dichloromethane), the complete conversion of heroin to O6-MAM was able to be prevented.

B195 The Transacetylation of Controlled Substances in Analytical Matrices

Bailey K. Davis, MPS, New York City Police Department Police Laboratory, Jamaica, NY; Jaclyn Beshlian, MFS, New York City Police Department Police Laboratory, Jamaica, NY; Anthony Chiusano, BS, New York City Police Department Police Laboratory, Jamaica, NY; Jennifer Yung, MS, New York City Police Department Police Laboratory, Jamaica, NY; Daniel Azevedo, BS, New York City Police Department Police Laboratory, Jamaica, NY*

Learning Objectives: The goals of this presentation are to: (1) inform the audience about specific casework instances at the New York Police Department (NYPD) Police Laboratory that inspired this research; (2) describe the resulting analytical research conducted in regard to the potential conversion of controlled substances while in the presence of acetyl group donors and/or acceptors; and (3) describe potential solutions to the issues observed during research and discuss future research goals.

Impact Statement: This presentation is extremely impactful for forensic science practitioners who analyze controlled substances. The information in this presentation may make them aware of potential conversions occurring for specific drugs of interest in evidentiary samples when analyzed by Gas Chromatograph/Mass Spectrometry (GC/MS) in common matrices.

Abstract Text: The transfer of acetyl groups from one compound to another is a reaction that has been extensively studied in organic chemistry. Compounds can act as either acetyl group donors or acetyl group acceptors. One compound considered an acetyl acceptor is acetaminophen (paracetamol), while aspirin (acetylsalicylic acid) is an acetyl donor. Both of these substances are commonly observed by the New York City Police Department (NYPD) Police Laboratory as diluents in illicit drug samples. Results obtained from Controlled Substance Analysis Section casework samples in 2023 and 2018 resulted in an in-depth review of the existing literature regarding reactions that involved acetyl donors and acceptors, but research pertaining to the forensic analysis of illicit drugs was sparse.[1,2] As a result, a wealth of experimental data was generated in order to ascertain whether transacetylation was occurring during casework analysis using the police laboratory's current procedures. It was found that in the presence of acetaminophen and/or aspirin, two pairs of substances underwent transacetylation, converting one compound into the other depending on whether an acetyl donor or acceptor was present. The first pair was heroin and 6-Monoacetylmorphine (6-MAM), and the second was 4-Anilino-N-Piperidine (4-ANPP) and acetyl fentanyl.

The results of this study have profound implications for the analysis of controlled substances and seized drugs in forensic science laboratories nationwide as they suggest that without proper safeguards to prevent transacetylation, certain substances may be incorrectly reported as present. Although some strategies aimed to minimize transacetylation proved effective, the pursual of analytical solutions to this issue by the NYPD Police Laboratory are ongoing.

B196 From Concept to Consensus: Advancing Standards for Dogs and Sensors in Detection Applications

Andrea Celeste Medrano, MSFS, Texas Tech University, Lubbock, TX; Paola Tiedemann, PhD, Texas Tech University, Lubbock, TX; Kenneth G. Furton, PhD, Florida International University, Miami, FL; Suzanne S Perry, Retired, Castalian Springs, TN*

Learning Objectives: This session will explore the collaborative work of the Organization of Scientific Area Committees (OSAC) Dogs and Sensors Subcommittee and the Academy Standards Board (ASB) Dogs and Sensors Consensus Body in shaping standard development for canine detection applications. Attendees will learn how these groups have developed comprehensive standards that support consistent, science-based practices across diverse detection missions—ranging from law enforcement operations to national security and military applications.

Impact Statement: The development of standards has become a crucial component of the canine detection community, helping to ensure consistency, reliability, and scientific integrity across operational practices. Within OSAC, the Dogs and Sensors Subcommittee—part of the Scene Examination Scientific Area Committee (SAC)—has been instrumental in this progress. The standard development process is rooted in scientific evidence, stakeholder consensus, and a rigorous, transparent review cycle. Experts from various sectors—including scientists, canine handlers, legal professionals, human factor experts, and veterinarians—collaborate to draft, refine, and validate standards through public comment periods and iterative revisions. To date, seven standards developed by the Subcommittee have been published by the ASB and are listed on the OSAC Registry, along with a comprehensive technical report on terms and definitions (currently on its second version revision). This presentation will highlight the groups' current pipeline on drafting upcoming standards, explain their structure, and discuss the critical need for their adoption by agencies employing canine detection teams.

Abstract Text: Attendees will receive updates on the current status of these efforts, including standards already published by Standards Developing Organizations (SDOs), documents listed on the OSAC Registry, proposed standards in the comment adjudication phase, and forthcoming drafts in development. Specifically, the standard for canine detection of human remains is currently in the comment adjudication phase; the illicit drug detection standard is undergoing public comment; standards for digital evidence detection and medical detection are in active development; and OSAC is reviewing final approvals for the proposed standard on training aid validation. To date, seven ASB standards developed by the Dogs and Sensors Subcommittee have been published by ASB and concurrently listed on the OSAC Registry.

Furthermore, this presentation will provide a detailed overview of the content and framework of the current standards documents, emphasizing the necessity for effective dissemination and rigorous implementation within the canine detection scientific community. It will also outline the strategic roadmap guiding the progressive development and nationwide integration of these standards. The efficacy and advancement of the Dogs and Sensors Subcommittee's efforts fundamentally depend on the sustained participation of researchers, practitioners, and stakeholders, whose collaborative contributions are vital to refining and validating standards that address the complex and evolving challenges inherent in diverse detection applications.

B197 Biological Sensor-Based Detection of Volatile Organic Compound Fractions From Human Remains

Rushali Dargan, PhD, Florida International University, Miami, FL; Ruchao Qian, MS, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL; Fantasia Whaley, MSFS*, Florida International University, Miami, FL; Joel L. Fuentes Carrasco, BS, Florida International University, Hialeah, FL; Daigoro Greco, BS*, Florida International University, Miami, FL*

Learning Objectives: Attendees will learn how Gas Chromatography-Fractionation (GC-F) can help identify decomposition odor fractions relevant to Human Remains Detection Dogs (HRDD) and how canine responses differ from necrophagous insects. Attendees will gain insights to improve synthetic decomposition canine training aids.

Impact Statement: This presentation will enhance the forensic science community's ability to develop standardized, evidence-based training aids for HRDD by identifying Volatile Organic Compound (VOC) fractions most relevant to canine detection. Applying these findings can improve the performance of HRDD teams in field operations, ultimately increasing efficiency and accuracy in locating human remains and delivering timely closure for affected families.

Abstract Text: Accurate detection of human remains is critical in forensic investigations, facilitating recovery, providing closure to families, and fulfilling ethical and cultural responsibilities. HRDDs remain the gold standard for locating whole or partial cadavers as no current electronic sensors or instruments have matched their sensitivity or operational versatility.[1] However, developing standardized and effective training aids for HRDDs remains a significant challenge. Natural aids offer complex, realistic odor profiles but face ethical, legal, and logistical constraints, while synthetic aids typically fail to replicate the dynamic complexity of decomposition odor.[2,3] Identifying the specific VOCs most relevant to biological detection is therefore essential for creating realistic synthetic aids and for understanding which compounds canines associate with human decomposition.

This study aimed to identify VOC fractions associated with human decomposition that elicit the strongest responses in two biological sensors: trained HRDDs and the necrophagous black blowfly *Phormia regina*. Using a GC-F approach, VOCs were collected from decomposing human and animal remains via Solid-Phase Microextraction (SPME) and separated into discrete time-based fractions. These fractions were collected on sorbent materials and presented to canines during controlled behavioral trials and to *P. regina* via Electroantennographic (EAG) recordings. This dual-biosensor approach enabled assessment of VOC subsets that triggered behavioral alerts in canines and antennal responses in *P. regina*, providing complementary insights into decomposition odor detection across vertebrate and invertebrate systems.

Results demonstrated that canines discriminated between odor fractions, showing differential alert rates, whereas *P. regina* exhibited relatively uniform antennal activation across fractions and did not differentiate between them as distinctly. These findings indicate fundamental differences in how the two biological sensors detect and prioritize decomposition-related chemicals. The results underscore the utility of GC-F for dissecting complex cadaveric odor profiles and isolating biologically relevant fractions. By integrating canine behavioral data with insect physiological responses, this study identifies candidate VOCs for developing standardized synthetic training aids for HRDDs and enhances understanding of how canines perceive decomposition odor.

B198 Detector Dogs: Advancing Drug Detection Operations Using Science at the United States Customs and Border Protection

Jonathan McGrath, PhD, U.S. Customs and Border Protection, Laboratories and Scientific Services, Houston, Tx; Armando Avallone, MS, U.S. Customs and Border Protection, Houston, TX*

Learning Objectives: After attending this presentation, attendees will understand: (1) how the United States Customs and Border Protection (CBP) uses canines to detect and interdict drugs and emerging drug threats at the border; (2) the science of developing drug training aids and learn how forensic drug chemists can use their expertise to advance the practice of law enforcement canine detection training and operations; and (3) how to collaborate with canine practitioners to design appropriate, high-quality training aid materials and robust canine trials to assess canine performance.

Impact Statement: This presentation will inform the forensic science community on strategies they can implement to develop and maintain quality controls for canine drug training aids. The accuracy and reliability of canine drug detection operations relies on the quality of training aid materials. Forensic scientists, and seized drug chemists in particular, are best positioned to provide expert knowledge and conduct analytical testing to ensure the quality of training aid materials.

Abstract Text: The United States CBP maintains one of the largest canine programs with more than 1,500 canine teams deployed at and between the nation's ports of entry that are trained to detect concealed humans, narcotics, firearms and ammunition, and currency as well as prohibited agriculture items and human remains. Canine training aids play an important role in the initial certification and the continuous proficiency testing of canines deployed for field operations. The CBP Laboratories and Scientific Services (LSS) is the agency's scientific and technical arm that tests and produces the materials used for narcotics training aids and advises CBP canine program stakeholders on training aid development. LSS has made great strides to advance the analytical testing capabilities and quality of canine training aids, and CBP is well-positioned to share its experiences to facilitate greater partnerships between forensic scientists and canine practitioners to strengthen law enforcement canine detection capabilities.

This presentation will provide an overview of CBP's canine detection programs and discuss opportunities for forensic laboratories to collaborate with canine detection teams to advance the implementation of evidence-based practices. CBP's canine drug detection programs are managed collaboratively by the Office of Training and Development, Office of Field Operations, and United States Border Patrol, each with unique operational missions and objectives. LSS produces training aids for these stakeholders consisting of cocaine, methamphetamine, heroin, ecstasy, marijuana, and fentanyl aids as well as pseudonarcotics training aids, which represent a single odor found in the chemical odor profiles of these drugs. LSS utilizes qualitative and quantitative methods to characterize the chemistry of training aid materials, and performs Solid Phase Microextraction/Gas Chromatography/Mass Spectrometry (SPME/GC/MS) to assess the materials' chemical odor profiles to better understand canine scent detection. LSS also partners with the CBP canine programs to evaluate the stability and performance of these training aids, and supports the development of new training aids to meet mission goals, particularly through the design of robust canine trials. Through increased knowledge sharing, continuous communication, and enhanced collaborations, CBP scientists and canine experts are applying rigorous scientific approaches that are feeding into evidence-based policies and implementation strategies.

As of 2020, approximately 16,000 canines teams are employed by state and local law enforcement agencies in the United States, which rivals the number of forensic scientists employed by all United States forensic laboratories at 15,600.[1] This presentation will demonstrate to forensic science practitioners how their existing scientific experience and expertise will contribute to the quality and implementation of law enforcement canine drug detection advancements.
